An update on the satellite interference to dark skies

Dr Priya Shah

Maulana Azad National Urdu University, Hyderabad, India

Abstract

This talk will focus on the satellite threat to observational astronomy. As a member of the Satellite constellation Working Group: Observatories sub group a recommendation was drafted for the Dark and Quiet Skies 2 Report, which shall be discussed. I shall also discuss the SatHub and the Education of observers about satellite constellations for regular citizens, amateur astronomers and professional astronomers and the Outreach activities planned. A recent update on the present status will be presented.

SIRI: A Risk Assessment Tool for Satellite Interference on Ground-Based Astronomy

Emma Louden

Yale University

Abstract

Ground-based telescopes have long been pivotal, generating the majority of astronomical data by volume and coverage. However, the influx of satellites is reshaping ground-based astronomy. Satellites now streak across once-clear fields of view, disrupting radio signals. In 2010, there were fewer than 1,000 satellites; by September 2023, there were over 9,000. This rise concerns astronomers, particularly with the impending launch of around 500,000 more satellites alongside the development of 30-meter, billion-dollar telescopes. The increasing saturation of our skies with artificial satellites threatens the functionality of ground-based observatories. To address this, we propose a proactive measure: identifying the most vulnerable ground-based astronomy cases and developing a ranking system to prioritize resource allocation. By determining which scientific investigations are most at risk from planned satellite constellations, we can prioritize the development of solutions, such as new space-based telescopes or advanced mitigation strategies. Our risk matrix, the Satellite Interference Risk Index (SIRI), categorizes ground-based astronomical cases based on threat level, mitigation abilities, and importance to the scientific community. This ranking system will inform policy decisions, helping space agencies and funding bodies decide which ground-based projects to continue funding, which projects will require space-based alternatives, and which ground-based instruments and observatories most need mitigation techniques.

The IAU Centre for the Protection of Dark and Quiet Skies Industry and Technology Hub - an update

Tim Stevenson[1], Patricia Cooper[2], Chris Hofer[3]

[1]SKAO. [2]Constellation Advisory, LLC. [3]Amazon Project Kuiper

Abstract

The Industry and Technology Hub of the IAU CPS has a number of functions in providing an interface to the satellite industry - operators and manufacturers (both systems and technology). Firstly, the Hub is an 'attractant' to bring industry stakeholders to the CPS and its Hubs and to promote common understanding of both the problem of dark and quiet sky and the potential solutions. Secondly, the I&T Hub offers support to industry in a number of ways, including briefings, background documents and active support in the form of Astronomer guides. Thirdly, the Hub meets a need for industry players to share experiences amongst themselves in terms of the efficacy of solutions and how to take dark and quiet sky considerations into account in design, mission planning and operations. Finally, the Hub is promoting the necessary research into further solutions both for the deleterious optical/infra-red effects and into mitigations in the radio wavelengths.

The Hub actively seeks out industry participation, and has been highly successful in attracting major actors and getting them to interact, begin to contribute to wider CPS activities such as observation campaigns and to share the understanding of the threats to ground based astronomy in order to address them.

This contribution provides an update to the work of the I&T Hub and looks forward to further developments in mitigations.

SpaceAble and the Dark Sky: Sky observation by and for citizen astronomers

Dr Cantegreil Julien[1], Yannis Zancanaro[1], Pr. Dr. Zouhair Benkhaldoun[2,3], Dr Franck Marchis[4,5], Dr Abdelkarim Boskri[2,3,1], Dr Raoul Canameras[6], Dr Tom Esposito[4,5], Dr Morgan Gray[6], Dr Ryan Lambert[4,5], Dr Pierre Janin-Potiron[6], Dr Benoit Neichel[6]

[1]SpaceAble. [2]Oukaïmeden Observatory. [3]Cadi Ayyad University. [4]SETI. [5]Unistellar. [6]Laboratoire d'Astrophysique de Marseille

Abstract

The proliferation of satellite constellations in orbit poses significant challenges to ground-based astronomical observations and space sustainability. Collaboration between institutional and private entities is essential to address the light pollution generated by these satellites, spanning from optical to radio frequencies, and mitigate debris impact on space operations.

To mitigate this pollution, accurate tracking of orbiting objects is crucial. SpaceAble, a French startup specializing in Space Situational Awareness (SSA), is developing a scalable optical sensor network to improve the accuracy of orbit predictions. Partnering with organizations like the IAU-CPS since 2022 and collaborating with citizen astronomers, SpaceAble aims to establish a global community dedicated to safeguarding space observation.

SpaceAble's initiatives include joining the France 2030 funding program with the DOSSA project - Decentralization of Space Situational Awareness, in partnership with Unistellar, to develop remote telescope control and image processing capabilities. DOSSA is also a collaboration with academic institutions like the Laboratoire d'Astrophysique de Marseille and Cadi Ayyad University, to enhance detection algorithms to improve sensitivity to smaller objects with deep-learning techniques.Furthermore, SpaceAble is working on commercializing standardized data for space traffic management and space weather, catering to both institutional and private sector needs.

This session provides an opportunity to showcase the progress and commitments of this international collaboration, inviting additional observatories to join efforts under the IAU-CPS to address orbiting object pollution for ground-based observations.

Project West Ford, the IAU's response, and the framing of the Outer Space Treaty 1961–1967

Dr John Barentine

Dark Sky Consulting, LLC

Abstract

Since the dawn of the Space Age, astronomers have contended with uses of outer space that sometimes conflict with their research goals and priorities. Military users in particular created early friction with the astronomical community as exemplified by the U.S. military program known as 'Project West Ford' (PWF). Against the backdrop of the emergent Cold War, the U.S. tested an 'artificial ionosphere' for radio propagation by placing thousands of copper dipoles into an orbiting belt. Despite the relative openness with which the U.S. conducted PWF, astronomers worried that the experiment would adversely impact ground-based (and future space-based) astronomy. The IAU expressed serious concerns about the planned PWF test at the XIth General Assembly, "warning of the grave moral and material consequences which could stem from a disregard of the future of astronomical progress". While PWF ultimately did no harm to astronomy, the affair informed the framing of Article IX of the Outer Space Treaty, which requires launching states to exercise "due regard" in conducting activities that could yield "potentially harmful interference with … the peaceful exploration and use of outer space". In this presentation I will review the history of PWF as it prompted astronomers of the era to react, providing important historical context for the ongoing issues involving astronomy and commercial space operators regarding large satellite constellations.

Toward an Enhanced Civil Space Situational Awareness System Based on Compact Semi-Professional Tools for Satellite Observation and Monitoring

Mr Vladimir Pashkovsky, Mr Stanislav Karpikov

StealthTransit Laboratories, StealthTransit, Germany

Abstract

The increasing number of satellites in low Earth orbit has revealed the limitations of current Space Situational Awareness (SSA) services and tools in accurately predicting trajectories of satellites and space debris within images. Previous reports have highlighted errors in time and position calculations based on available data (NORAD, for example). There remains a shortage of public services for predicting trajectories and coordinating observations. This process involves estimating probabilities, variations in traffic density by season and location, and classifying brightness and iridescence, among other factors. A service implementing a big data approach would be suitable for all kinds of tools, including post-processing techniques, trail avoidance strategies, observation scheduling, or employing mid-exposure shuttering (following the approach proposed by StealthTransit).

The task of gathering information of hundreds of thousands objects can be done through a distributed system – data grid (Space Surveillance Grid) engaging both professional and amateur astronomers. This study analyses the requirements for such a system and discusses an approach that integrates relatively inexpensive (and thus accessible for widespread use) yet self contained tools based on individual telescopes and cameras, joined into a global data collection network.

The potential scale and parameters of such a system are examined. For instance, it could enable the creation of a real-time 2D map of the sky featuring tracked objects, with some level of estimation for the third coordinate, with the error depending of the number of devices in a given area.

Active spaceborne RFI mitigation strategy for VLBI

Matthias Schartner, Benedikt Soja

ETH Zurich

Abstract

The increase in radio frequency interference (RFI) from satellites in space is causing issues for Very Long Baseline Interferometry (VLBI) observations. In particular, satellite mega-constellations such as Starlink pose a significant threat since these satellites will emit signals in the upper-frequency range of the VLBI Global Observing System (VGOS). The power of these signals may saturate the amplifiers of VGOS antennas, causing nonlinearities within the observations.

As an active mitigation strategy, we have extended the VLBI scheduling software VieSched++ to account for satellite orbit information in the form of two-line-element (TLE) files. Based on this information, observations in the direction of potentially harmful satellites can be avoided to reduce the impact of spaceborne RFI. However, this strategy adds additional constraints to the scheduling algorithm, affecting the efficiency of VLBI observations. We will share simulation results comparing the impact of these constraints on parameter precision with and without our active avoidance approach. While our active mitigation approach helps, we will also discuss its limitations and future development steps.

Additionally, we will highlight the deployment of a user-friendly database (https://satdb.ethz.ch/) to simplify access to satellite TLE information within a specific time span and based on an observed frequency sequence. The database is publicly accessible via a web interface and an application programming interface (API).

Satellites' Radio Frequency Interference: its impact on radio astronomy.

Dr Nadeem Oozeer

South African Radio Astronomy Observatory (SARAO), Cape Town, South Africa. Centre for Radio Astronomy Techniques and Technologies, Department of Physics and Electronics, Rhodes University, South Africa

Abstract

Radio frequency Interference (RFI) is any unwanted radio signal that affects/impacts astronomical data. RFI comes from different sources, both artificial and natural. By analysing radio data from the MeerKAT, I will present the various sources of RFI around the future Square Kilometre Array (SKA) mid-site, and how it impacts radio astronomy.

Protection of Dark and Quiet Skies at the National Level: Conclusions and Recommendations

LLM. Yana Yakushina[1], Marieta Valdivia Lefort[2]

[1]University of Ghent. [2]University College London

Abstract

The protection of dark and quiet skies (D&QS) has garnered heightened attention across various regulatory levels. This surge in interest is attributed to the widespread proliferation of artificial light at night (ALAN), leading to terrestrial light pollution (LP), and separately, an escalating deployment of mega-constellation satellites in low-earth orbit (LEO), resulting in orbital light and radio spectrum pollution. Changes in nighttime brightness have resulted in complex concerns ranging from detrimental effects on astronomical observations to adverse impacts on the environment. These concerns have prompted some national states to take action to address challenges related to the disappearance of D&QS with a focus on the adoption of ground-based light and noise pollution prevention measures.

Following the preliminary work presented at the IAUS385, this presentation will introduce the final conclusions and recommendations of the research conducted by the IAU CPS Policy Hub, WP 2, National Analysis team. The team has investigated over 70 different jurisdictions worldwide to identify approaches towards protection D&QS. The presentation outlines the research methodology, delivers conclusions and recommendations, and provides illustrative examples from national regulatory frameworks. For a more comprehensive analysis, the research was focused on three primary dimensions: (1) protection of dark skies (addressing aspects of LP); (2) protection of quiet skies (addressing aspects of radio/noise pollution); and (3) satellite regulations (encompassing registration, authorization, and technological requirements). Overall, the work builds an understanding of national approaches aimed at D&QS protection and allows for the identification of potential regulatory improvements in this realm.

The scientific importance of Laser Guide Star AO Systems and impacts arising from the protection of LEO satellites.

Dr. Warren Skidmore[1], Dr. Julian Christou[2]

[1]Thirty Meter Telescope. [2]NOIRLab/Gemini Observatory

Abstract

The scientific output of ground based observatories is becoming increasingly dependent on the us use of laser support adaptive optics systems. I will show that as we move toward the era of the ELTs, the majority of the envisioned science will depend on laser guide star supported AO. Presently, any ground based observatory related to the United States is required to adhere to the US Laser Deconfliction Policy, which means that laser propagation from the ground has to stop as and when set by the Laser Clearinghouse. With the continuing rise in the number of LEO satellites, a situation will arise where laser supported adaptive optics operations will become essentially impossible. I report on efforts to evaluate the risk to space assets from astronomical lasers and moves to adapt the policies to enable laser guide star supported science by US facilities.

[7]Steward Observatory, AZ, USA

Abstract

SatHub is one of the four hubs of the IAU Centre for the protection of the Dark and Quiet Sky from Satellite Constellation Interference (IAU CPS). SatHub focuses on observation campaigns, brightness data analysis and software curation to improve our understanding of the impact of satellite constellations on astronomy and observers worldwide. That includes online services hosted in concert with our contributing members that simplify satellite constellation mitigation in astronomical observation planning. In this contribution we will give a summary of services offered by SatHub and its members and discuss the current status of satellite constellation observation campaigns for several operators and across the electromagnetic spectrum. Online services such as SatChecker and the Satellite Constellation Observation REpository (SCORE) will be presented.

Spectrum Management at ALMA

Dr Giorgio Siringo[1,2], Dr. Sean Dougherty[1]

[1]Atacama Large Millimeter/submillimeter Array - ALMA. [2]European Southern Observatory - ESO

Abstract

We present here the work carried out by the Joint ALMA Observatory Spectrum Management Office (JSMO) and its commitment to RFI protection and prevention at the ALMA site. Coordination efforts between the Chilean national radio-communication authority SubTel and the ALMA European and North American representatives in Chile in 2023 made possible a 10-year renewal of the exempt resolutions that give ALMA radio protection in a 30 km radius and coordination in a 120 km radius on Chilean territory. Thanks to the efficient collaborative relationship with SubTel, we are evaluating the possibility of extending the two areas to the neighboring territories of Argentina and Bolivia. Another topic of conversation with SubTel is to impose a minimum distance from ALMA to new satellite-constellation gateway stations installed on Chilean territory.

Our office is also involved at both national and international levels in developing synergies with groups active in the field of spectrum management, e.g. the radio committee of the SoChiAs, the multidisciplinary initiative CLEOSat, the CARF in Europe, the NRDZ in the USA. An aspect of particular importance for ALMA is the extension of the ITU Recommendations related to Radio Astronomy to cover frequencies from 275 GHz upwards , where more than 70% of ALMA's observation spectrum falls, and which is currently without any protections. We plan to maintain active participation in the preparatory work for the next WRC in 2027.

The potential impact of satellite constellations on Cosmic Microwave Background experiments

Dr Mike Peel[1,2], Dr Dave Clements[1], Dr Allen Foster[3]

[1]Imperial College London. [2]IAU CPS. [3]Princeton

Abstract

Cosmic microwave background experiments observe large angular scale emission at extremely high sensitivity at 10-1,000GHz. At these frequencies, satellites both actively transmit (currently around 10GHz, extending up to ~200GHz in the future), and will be thermal black bodies/reflectors of thermal emission. While small numbers of satellites can be ignored as glitches, the dramatic increase in satellite numbers over recent years means this component has to be taken into account with future ground-based CMB experiments. This presentation will describe work so far to understand the effect of satellites on CMB experiments, using observations of individual satellites by the Atacama Cosmology Telescope (ACT), the South Pole Telescope (SPT), and the SCUBA-2 instrument on the James Clerk Maxwell Telescope (JCMT). The presentation will also cover the extrapolation of these observations to make predictions of the overall impact on observations by entire satellite constellations.

Overview of ESA Space Debris Mitigation Requirements and compliance verification guidelines applied for dark and quiet skies

Dr Jan Siminski[1], Beatriz Jilete[2]

[1]ESA. [2]GMV for ESA

Abstract

The ESA Space Debris Mitigation Policy was updated in October 2023 accounting for the new ESA Zero Debris Approach. The new ESA Space Debris Mitigation standard (ESSB-ST-U-007, which exceeds the previous standard ECSS-U-AS-10C Rev.2) specifies design and operational measures that a mission needs to adopt through its lifetime to prevent space debris release and proliferation, control system break-up risk, control collision risk, control system failure risk, improve orbital clearance, assure safe re-entry and minimise impact on astronomy.

The requirements for the protection of dark and quiet skies encompass the limitation of optical and radio frequency interferences with ground and LEO astronomy, prediction and sharing of information of the brightness during the mission design, and promotion of mitigation actions.

The paper will explain in detail the new dark and quiet skies requirements included in the standard.

In addition to the mitigation standard, ESA is preparing an update to the compliance verification handbook to be released before summer 2024. The handbook provides the guidelines on verification methods (e.g. prediction of brightness during mission design phase) and recommend mitigation measures in support to ESA missions to facilitate the compliance with the ESA Space Debris Mitigation requirements. The new version will be aligned with the current space debris mitigation standard. The paper will give an overview on the methods, guidelines and formulas that mission developers would be required to follow in order to be compliant with the new standard.

List of radio astronomy stations as a database for sharing and compatibility studies

Mr Boris Sorokin[1,2], Mr. Federico Di Vruno[1,2], Mr Mike Peel[3,2]

[1]Square Kilometre Array Observatory. [2]IAU CPS. [3]Imperial College London

Abstract

In the evolving landscape of spectrum sharing between radio astronomy observatories and satellite operators, the interplay between them becomes more and more important. Historically it was national administrations to support data exchange between different radio spectrum users. However, with rapid satellite development a need for a more global approach arises.

Our discussion extends to the development and utilization of a CPS-based database, incorporating data from a snapshot of the Master International Frequency Register (MIFR) to house radio astronomy observatories' characteristics. This database not only serves as a vital resource for sharing and compatibility studies within the IAU CPS framework but also addresses gaps in existing registries by including data from unfiled observatories, like the South Pole Telescope.

Furthermore, we introduce a novel tool designed to help those with access to the ITU database, allowing for efficient retrieval of radio astronomy station data. This tool, aimed at both the radio astronomy and satellite communities, promises to streamline the process of conducting sharing and compatibility studies by providing comprehensive access to essential parameters, including station and antenna specifics, frequency bands, and operational details. This initiative represents a significant step forward in ensuring the harmonious coexistence of satellite and radio astronomy operations, bolstering the efficacy of global regulatory frameworks.

Hunting for satellite trails in astronomical images with machine learning

Dr. Jeremy Tregloan-Reed, Ms María Romero-Colmenares

Instituto de Astronomía y Ciencias Planetarias, Universidad de Atacama

Abstract

The proliferation of Low Earth Orbit (LEO) satellite constellations raises concerns for ground-based and space-based astronomy due to their impact on the night sky. Research groups like CLEOsat and the IAU's CPS are working to quantify this impact, but doing so requires dedicated observing time, diverting resources from scientific astronomy.

This work proposes a solution using pre-existing data from wide-field surveys, which inevitably capture satellite trails. However, analyzing terabytes of data containing a mix of clear and contaminated images is computationally expensive.

We address this challenge by developing a supervised machine learning algorithm trained on datasets with equal numbers of clear and satellite trail-contaminated images. This approach leverages existing "wait and catch" observations from the CLEOsat network, ensuring balanced training sets and mitigating potential bias.

Our algorithm is currently undergoing validation on public data from WASP and HATNet, with initial results showing promising accuracy (96%). This work paves the way for utilizing machine learning to efficiently analyze existing astronomical data and alleviate the burden on dedicated observing time, ultimately aiding astronomers in understanding and mitigating the impact of LEO constellations on the night sky.

CLEOsat: Combating Satellite Constellation Impacts on Astronomy through Research, Policy, and Collaboration

Dr. Jeremy Tregloan-Reed

Instituto de Astronomía y Ciencias Planetarias, Universidad de Atacama

Abstract

The Chilean Low Earth Orbit Satellite (CLEOsat) group actively researches the impact of satellite constellations on astronomy through collaborative observational campaigns with the IAU Centre for the Protection of the Dark and Quiet Sky from Satellite Constellation Interference (CPS), currently focusing on AST SpaceMobile's Bluewalker 3 and Starlink V2 mini-satellites.

Additionally, CLEOsat conducts independent campaigns utilizing its network of telescopes across Chile, Spain, Mexico, Vietnam, and South Korea, aiming to characterize the multi-wavelength reflective brightness of OneWeb and Starlink satellites and assess the accuracy of supplemental Two Line Elements (TLEs) for orbit determination.

Beyond research, CLEOsat actively contributes to national and international policy and regulations. Members participate in developing regulations to minimize ground-based light pollution and protect observatories in Chile. Notably, they provide expertise and advice to the Chilean Ministry of Transport and Telecommunications regarding the licensing of ground stations used by satellite operators. Furthermore, CLEOsat members represent Chile within the IAU CPS policy hub group of friends, contributing to international dialogue and policy formation.

This multifaceted approach empowers CLEOsat to effectively address the challenges posed by satellite constellations, ensuring the continued viability of astronomical research and the protection of the night sky.

Engaging with diverse stakeholders about satellite constellations: foundations of the CPS Community Engagement Hub

Dr John Barentine[1,2], Ms Jessica Heim[3,2]

[1]Dark Sky Consulting, LLC. [2]IAU CPS. [3]University of Southern Queensland

Abstract

Large satellite constellations are rapidly remaking the continuum of environment from Earth to space in important ways, yet the input of many affected people and groups continues to be left out of decisions affecting the uses of outer space. The IAU Centre for the Protection of the Dark and Quiet Sky from Satellite Constellation Interference (CPS) aims to help bridge this gap where the effects of constellations on astronomy is concerned. The mission of the CPS Community Engagement (CE) Hub is to provide stakeholders outside of professional astronomy with a venue in which to be heard and to help clearly communicate their views and opinions to a wider audience. This presentation will focus on how CE Hub is engaging with stakeholders, raising awareness of the issue and providing important factual information and resources to inform ongoing discussions. We will review events, conferences, and actions of the astronomical community that led to the creation of the CE Hub and informed its foundations. We will then describe how the outcomes of those interactions have been incorporated into the CE Hub strategy and its initial plans and activities.

OneWeb Satellites Photometric Modelling: Specular and DiffuOneOneWeb satellites Photometric Modelling: Specular and Diffuse Components

Maria Isabel Romero-Colmenares[1,2], PhD Jeremy Tregloan-Reed[1,2]

[1]INCT - Universidad de Atacama. [2]Chilean low Earth orbit satellite (CLEOsat)

Abstract

The proliferation of Low Earth Orbit (LEO) satellite constellations, with tens of thousands planned from companies like OneWeb and Starlink, raises concerns for ground-based astronomy. These satellites leave trails in astronomical images, impacting research across various disciplines. Studies have measured the reflective brightness of Starlink satellites (Boley et al. 2022; Tregloan-Reed et al. 2020, 2021; Tyson et al. 2020) to quantify these risks.

This study investigates the impact of the OneWeb constellation and its reflective brightness, whilst, considering satellite design, solar phase angle, range, effective albedo, and effective cross-section. Observations of over 300 OneWeb satellites from the 0.6m telescope at the Chungbuk National University Observatory (CbNUO), combined with diffuse sphere models (e.g. Boley et al. 2022; Pradhan et al. 2019), demonstrate the feasibility of identifying operational ("On-station") and non-operational ("Off-station") satellites based on their brightness. Additionally, the phase angle can be used to provide an estimate of the observation direction. This research provides valuable insights into the impact of OneWeb constellations on astronomical observations and lays the groundwork for further mitigation strategies.

Determining the efficiency, accuracy, and precision between supervised and unsupervised machine learning algorithms in hunting for satellite streaks in astronomical survey images

Isabel Romero-Colmenares[1,2], Jeremy Tregloan-Reed[2,1]

[1]INCT - Universidad de Atacama. [2]CLEOsat

Abstract

The increasing presence of LEO satellite constellations like Starlink raises concerns for astronomical observations. These satellites leave faint trails, impacting data quality across various disciplines, including space telescopes. Machine learning offers a promising avenue for addressing this challenge through anomaly detection techniques.

Both supervised and unsupervised methods can be utilized. Supervised learning requires pre-labeled data, while unsupervised methods identify deviations from "normal" astronomical images. Ground-based observations from diverse locations provide valuable data for training and validating these models, ultimately enabling the identification and mitigation of satellite constellation trails.

Research groups like CLEOsat and the IAU's CPS have studied the impact of LEO satellites, relying on observations from various observatories at the expense of dedicated science time. ML offers a solution by automatically identifying satellite trails in existing data, such as long-term astronomical surveys. Unsupervised methods have proven successful in other astronomical applications, prompting its exploration for satellite trail detection.

This work presents the development and accuracy of an unsupervised ML method for classifying images with and without satellite trails. While both supervised and unsupervised methods could potentially identify contaminated images, their comparative performance remains unaddressed. This research aims to compare their effectiveness in detecting satellite trails in publicly available surveys, ultimately providing a valuable tool for astronomers and satellite operators to study and mitigate these potential impacts.

The Impact of Satellite Constellations on the Vera C. Rubin Observatory Legacy Survey of Space and Time

Professor Zeljko Ivezic[1,2], Dr. Meredith Rawls[2,3,4]

[1]AURA/Vera C. Rubin Observatory. [2]University of Washington/DiRAC Institute. [3]Vera C. Rubin Observatory. [4]IAU CPS

Abstract

Beginning in 2025, the Rubin Observatory Legacy Survey of Space and Time (LSST) will survey the southern sky with unprecedented cadence and depth and open new windows to discovery in all areas of astrophysics. At the same time, satellite companies are launching new hardware into low-Earth orbit (LEO) at a rapid pace, and estimates predict about 50,000-100,000 active LEO satellites during the decade of LSST Operations. This presentation will begin with an overview of how streaks from LEO satellites due to reflected sunlight can affect LSST data products and science goals. It will then discuss work underway to quantify and mitigate the science impacts, such as modifying the observing strategy to avoid some satellites, identifying glints and flares, and detecting streaks so the LSST alert stream does not include them.

The effect of behavioral norms on developing Dark and Quiet Sky Protection frameworks in emerging spacefaring nations

Tamara Blagojevic

Space Court Foundation. OSA Consulting LLC. IAU CPS

Abstract

The preliminary results of the International and National Analysis teams of the IAU CPS Policy Hub showcased multiple benefits of implementing integrative, multidisciplinary and holistic research methods.

The International lens analysis revealed the necessity of due consideration of appropriate environmental principles and norms in dark and quiet skies protection, along with the Space Law framework. The benefits of an integrative approach were evidenced by the recent progressive shift in consciousness around space sustainability, which further influenced the emergence of various initiatives in the international and regional Space Law frameworks.

The examination of particular examples of the national Dark and Quiet Sky protection frameworks, showcased that many emerging space faring nations carry out initiatives which can support the progressive development of the protection of dark and quiet skies and astronomical activities.

As a result of the overview through both international and national lenses, behavioral science mechanisms have been identified as a cohesive element that can enable a more integrative, inclusive and culture sensitive approach. Behavioral science incentives have been tested in the environmental sector and showcased positive results in influencing policy making globally. Moreover, since nonbinding legal instruments, known as soft law, can guide the development of binding, hard laws, human behavior inspiring normative developments should be considered early on in the norm life cycle.

This presentation will examine the adequacy of the behavioral science mechanisms to contribute to the progressive development of the Dark and Quiet Skies protection framework, by analyzing particular initiatives and incentives in exemplary national contexts.

The IAU CPS - Characterizing Threats and Catalyzing Mitigations

Richard Green[1,2], Connie Walker[3,2], Federico Di Vruno[4,2]

[1]University of Arizona. [2]IAU CPS. [3]NSF's National Optical/Infrared Astronomy Laboratory. [4]Square Kilometre Array Observatory

Abstract

As astronomers are acutely aware, satellite constellations in Low Earth Orbit create sunlight streaks impacting optical/infrared observations and produce radio emissions affecting radio observations. While technology advancement pushes for more and larger satellites, measurements also show effective approaches to reducing effects on optical/IR and radio observations. In addition to radio communication signals, electronics in satellites create unintended low-frequency emissions that are detectable from the ground.

The IAU's Centre for the Protection of the Dark & Quiet Sky from Satellite Constellation Interference (IAU CPS) is taking multiple approaches to mitigate negative impacts. At least 12 operators meet under their auspices to share best practices and understand astronomical concerns. Observing campaigns are organized, and predictive software for position and brightness of satellites impacting planned observations is well into development. Educational videos about satellite constellations are available, and ongoing efforts are underway to engage with broader interested groups. CPS-affiliated policy and space law experts have developed and are refining recommendations for ultimately turning best practices into a model regulatory framework. Through the efforts of the IAU and other astronomy organisations, UN COPUOS is now adopting a five-year agenda item to consider astronomy and satellite constellations and the ITU-R is discussing protections for radio-quiet zones and radio astronomy bands from satellites. The IAU is leveraging its international constituency to address this urgent global issue.

Creating educational resources to inform and engage diverse stakeholders on satellite constellation issues

Jessica Heim[1,2], Dr. John Barentine[3,2]

[1]University of Southern Queensland Centre for Astrophysics. [2]IAU Centre for the Protection of the Dark and Quiet Sky from Satellite Constellation Interference. [3]Dark Sky Consulting, LLC

Abstract

The IAU Centre for the Protection of the Dark and Quiet Sky from Satellite Constellation Interference (CPS) Community Engagement (CE) Hub was established to provide stakeholders outside of the professional astronomy community with a venue in which to be heard and to help clearly communicate their views and opinions about large satellite constellations to a wider audience. However, in its efforts to engage with various constituencies on the topic of satellite constellations, CE Hub found that some stakeholders felt that they did not have enough information on the subject to form an opinion. While many were aware of the increasing numbers of satellites launched in recent years and that many of these were intended to provide broadband internet services, they were often not aware of more details related to these activities. Thus, CE Hub decided to develop unbiased, fact-based educational materials to help fulfill the need for resources on this subject readily understandable by the public. In this presentation, we will give a brief summary of the CE Hub's experience with this initiative to date; present some of our educational materials and resources; and discuss current and anticipated challenges in our efforts to aid in increased awareness of and interest in satellite constellation issues.

A look into preliminary impacts of satellite constellations on amateur astronomers' activities and research

Jessica Heim

University of Southern Queensland Centre for Astrophysics. IAU Centre for the Protection of the Dark and Quiet Sky from Satellite Constellation Interference

Abstract

The advent of large satellite constellations has become a subject of interest and concern for the field of professional astronomy. Increasing work is being done to better quantify the current and potential impacts to various subfields of astronomical research and to identify possible mitigations to reduce data loss and other challenges. However, little research has been conducted with the aim of exploring specifically, the nature and extent of impacts on amateur astronomy activities. In this presentation, I will present findings from surveys distributed to amateur astronomers. The purpose of these surveys was to obtain data that can help to understand both qualitative and quantitative impacts of large satellite constellations on the observations and research of these communities and to inform possible ways forward to minimize adverse effects on amateur astronomy activities.

Satellite education: "No, it's not a UFO, it's Starlink"

Dr Samantha Lawler

University of Regina

Abstract

Satellites are already changing the night sky worldwide, and many other companies are lined up to follow the same operational model. Despite efforts to reduce their brightness, Starlink satellites are easy to observe in the night sky, especially shortly after launch when they form "trains" and very low orbital altitudes while they gradually raise to their operating orbits. These have been seen all over the world by users of the night sky, whether or not they have the funds or government approval to use Starlink internet. Thus far, satellite operators' messaging to the public has been primarily focused on the services they aim to provide, but they do not appear to have put much emphasis to date on educating the general public about these highly visible satellites, or about the increasing number of satellites and rocket body re-entries that can be seen around the world. The lack of public education about these easily visible phenomena means that local astronomy departments in universities and amateur astronomy clubs have received a large burden of UFO calls from the general public, and spend a large amount of time doing this education work for free for large, for-profit private companies. In this talk, we provide some pointers for satellite operators to educate the general public about the changes that their activities are causing in the night sky.

The Impact of Large Satellite Constellations on Optical Astronomy

Dr. Constance Walker

IAU CPS. NSF's NOIRLab

Abstract

The deployment of communication satellite constellations in Low Earth Orbit (LEO) may represent a valuable step forward in improving world connectivity. However, the sun-reflected luminosity and radio-frequency emissions from a large number of satellites can have a serious impact on astronomical observations, as well as on the pristine appearance of the night sky. In recent years, various strategies for co-existence in terms of optical astronomy have been developed. There are now better models and data for satellite brightness, which are key to enabling mitigation, active avoidance, or use in compliance checks. Future observations of commercial LEO satellites will determine, for instance, whether some coatings and Bragg mirrors on reflective surfaces of Starlink satellites will help and how well. For spectroscopy, better modelling and understanding of satellite spectra will enable the emission from satellites to be calibrated out of astronomical data. Autonomous imagers on large spectroscopic facilities can help identify when an exposure was contaminated. For observatories, there are software solutions for streak detection and elimination that may help. During the presentation, we will discuss mitigation strategies through software and observation and provide updates in the areas of policy, industry and community engagement, some of which is being led by the IAU Centre for the Protection of the Dark and Quiet Sky from Satellite Constellation Interference.

Characterising unintended emission from satellite constellations with LOFAR

Dr Hao Qiu

SKA Observatory

Abstract

With the recent rapid development of satellite constellations, we face an increasingly challenging radio spectrum environment for observations. While the communication frequencies of these satellites are already known to the international community and regulated by the International Telecommunication Union (ITU), instruments onboard satellites are prone to generate certain electromagnetic leakage. Recent studies such as Di Vruno et al. (2023) and Grigg et al. (2023) have revealed unintended emission from the starlink satellite constellations where strong radio frequency interference has been observed at 110-188 MHz for unknown reasons. We present results from an extended observing campaign with the LOFAR radio telescope, focusing on Starlink, OneWeb and other satellite systems, to discuss the statistical impact of such unintended electro-magnetic radiation(UEMR) on low frequency radio astronomy and possible mitigation solutions.

EPFL Coordinates Research and Community Interests in Switzerland for the Protection of Dark and Quiet Skies

Stephan Hellmich[1], Carolyn Marie Crichton[1,2], Mathieu Udriot[1], Adrien Saada[1], Emmanuelle David[1], Jean-Paul Kneib[1]

[1]EPFL Laboratory of Astrophysics. [2]SKACH

Abstract

EPFL is facilitating the Swiss conversation on Dark and Quiet Skies through multiple initiatives. To unite EPFL's forces in the domain of sustainability in space, eSpace recently launched the Sustainable Space Hub (SSH). In order to coherently manage and foster the growth of these topics at EPFL, the hub connects the individual projects in a workflow that rests on three intertwined domains: measure, understand, and act. The presentation will focus on the activities within these domains related to the Dark and Quiet Skies initiative. The research initiatives that we will present are: (i) a project that evaluates the influence of space activities on astronomical observations using the methodology of the Space Sustainability Rating (SSR) with the goal of extending SSR by a new module such that it can account for that influence of future space missions, (ii) a research project to develop methods to detect satellites and space debris in large astronomical data archives that will help to better understand the growing influence of space objects on astronomical observations, (iii) tools that support engineers to incorporate space sustainability aspects already during mission design and (iv) community building activities to raise the voice of Swiss experts to for the Swiss delegation to the UNCOPOUS facilitated by the SKACH (Square Kilometre Array Switzerland). With this contribution we will help stimulate further activities aimed at bridging the gap between scientists, industry and policy makers in understanding and quantifying sustainability in space.

Development of a Python script for calculating orbital parameters and satellite magnitude: Validation through observational data from BlueWalker 3

AYOUB ABDOU[1], Professeur Zouhair Benkhaldoun[2], Doctor Abdelkarim BOSKRI[1], PhD Student Hamid IDELBACHA[1,3]

[1]Oukaimeden Observatory, High Energy Physics and Astrophysics Laboratory, FSSM, Cadi Ayyad University, Marrakech, Morocco.. [2]Oukaimeden Observatory Director, High Energy Physics and Astrophysics Laboratory, FSSM, Cadi Ayyad University, Marrakech, Morocco.. [3]SpaceAble, Paris, France

Abstract

In this abstract, we present our developed Python script for processing images of artificial satellites and space debris observed through telescopes at the Oukaimeden Observatory. The script calculates the orbital parameters and apparent magnitudes of observed objects, allowing for calibration of their luminosity to standard parameters such as distance and phase angle. to allow a direct comparison of their reflective brightness in different observations. Validation results will be present from observational data of the bright constellation BlueWalker 3, confirming the reliability and accuracy of the script.

Enhancing Satellite Trajectory Monitoring: A Machine Learning Approach for Anomaly Detection and Classification

PhD Student IDELBACHA HAMID[1,2], Dr. Olivier Beltramo-Martin[2], Pr. Zouhair Benkhaldoun[1], Dr. Mohamed Kaab[1,3], Dr. Abdelkarim Boskri[1], PhD Student Ayoub ABDOU[1]

[1]Oukaimeden Observatory, High Energy Physics and Astrophysics Laboratory, FSSM, Cadi Ayyad University, Marrakech, Morocco.. [2]SpaceAble, Paris, France. [3]National School of Applied Sciences of Beni Mellal, Sultan Moulay Sliman University, Beni Mellal, Morocco

Abstract

Given the continual increase in the number of satellites in orbit, there is an escalating need to enhance trajectory models and operational risk management to gain a deeper understanding of orbital anomalies, such as unexpected changes in a satellite's orbit, which can have a significant impact on satellite operations and threaten human and financial resources. This study aims to employ machine learning techniques to identify abnormal or divergent changes in satellite trajectories, from datasets containing multiple sets of Two-Line Elements (TLEs). The automatic detection of these behaviors has the advantage of avoiding the computation of satellite position and velocity. In this case, which is an unsupervised framework, we have selected the LOOP(Local Outlier Probability), One-Class SVM(Support Vector Machine), and Isolation Forest methods. We choose these methods for their different perspectives on density and distance. Once anomalies are detected, it is interesting to categorize them based on their causes using supervised machine learning methods, namely Random Forest, SVM, and artificial neural networks. The quality of classification is evaluated using standard metrics such as the confusion matrix, precision, recall, and F1 score, with achieved results of an average precision of 89\%, a recall of 90\%, and an F1 score of 88\% for four anomalies classes: Propulsion, Deliberate, Battery, and AccidentalCollision.

The Development of Dark and Quiet Skies Standards in Government and Industry

Dr Andrew Williams[1,2], Dr Sara Lucatello[3,4]

[1]European Southern Observatory. [2]International Astronomical Union CPS. [3]European Astronomical Society. [4]INAF

Abstract

The astronomical community has made significant strides in highlighting the ramifications of satellite constellations within political and industrial spheres. Despite this success, the absence of specific government regulations safeguarding optical reflections remains a concern. Current measures, albeit limited, are in place under the auspices of the International Telecommunication Union (ITU). This presentation focuses on the initiatives undertaken by the European Space Agency—the development of the Space Debris Mitigation Standard, and also the European Union, Space Sustainability Labels. Remarkably, these standards may represent a crucial milestone as the first mandatory directives addressing the preservation of dark and quiet skies. In the absence of comprehensive regulatory frameworks and their protracted timescale for development, the establishment of voluntary standards and guidelines becomes imperative.

This talk reviews the progress of these mandatory and voluntary standards, reviewing their efficacy and potential for future development. By examining the evolving landscape of dark and quiet skies standards, we provide insights into the ongoing efforts, challenges, and prospects within the astronomy community.

Protection of Dark and Quiet Skies: Recommendations for the decision-making process

Marieta Valdivia Lefort[1], Robert Massey[2]

[1]University College London. [2]Royal Astronomical Society

Abstract

The protection of dark and quiet skies (D&QS) is starting to get more attention from governments and interest groups worldwide due to the work done by astronomical and environmental societies in this respect. This work has involved raising awareness on the proliferation of artificial light at night (ALAN) and the increased terrestrial light pollution (LP), an also the escalating deployment of mega-constellation satellites in low-earth orbit (LEO) affecting astronomical observations. Nevertheless, and despite these efforts, the process of achieving national policy and legislation on the protection of D&QS has not been straightforward or sufficiently effective in many cases.

Considering the above, this presentation gives some recommendations to be taken into account in the negotiation and decision-making process regarding the protection of D&QS at the legislative level. Thus, this presentation highlights both the strategies necessary to promote this issue and include it in the political agenda (advocacy, negotiating with interest groups, involving charities, etc.) and the elements of the decision-making process that could hinder the legislative process but that should indeed be considered (bureaucracy, legislative interest in the matter, etc.). Although with more emphasis on the British experience in this respect, the recommendations presented here can be extended to the rest of the countries.

Simulating the impact of satellites on astronomical observations

Dr Ana Cecilia Soja, Pedro Henrique Rocha de Andrade, Maycon Jorge Deláqua da Silva

Fluminense Federal Institute

Abstract

A new era begins in Astronomy, with the launch in the coming years of several terrestrial and space telescopes that will increase by thousands of times the amount of data we have available to understand the sky. Along with the challenge of analyzing this unprecedented volume of information, there is a difficulty that is not well understood to date: the negative impact that satellite luminosity can have on observations. It is estimated that a project like the Vera Rubin telescope, for example, will have 30 to 40% of its images compromised. From a political point of view, we know limiting these launches is unfeasible. For this reason, the alternative for observational Astronomy is to develop new strategies to deal with the satellite luminosity contamination. One of them is building image processing pipelines that allow terrestrial observations to continue. Many working groups have already developed mitigation strategies and carried out tests of their efficiency on real images. In our research, we investigated the models used to date and their efficiency. It became clear that the simplest alternative, the single mask, is not efficient enough to make the images scientifically suitable. Therefore, it is necessary that more complex models, for example, that adapt the variation in luminosity to the trail, are developed.

Enhancing Satellite Observation Capabilities: The Role of Oukaimeden Observatory

Dr Abdelkarim BOSKRI, Prof Zouhair Benkhaldoun, PhD Student Ayoub Abdou, PhD student Hamid Idelbacha

Oukaimeden Observatory, High Energy Physics and Astrophysics Laboratory, FSSM, Cadi Ayyad University, Marrakech, Morocco.

Abstract

The Oukaimeden Observatory, as a proud partner of the IAU-CPS center, plays a crucial role in satellite observation initiatives. Equipped with a diverse array of professional and amateur telescopes, the observatory offers comprehensive satellite observation services and actively engages in daily monitoring activities. Moreover, it serves as a hub for collaboration with other observation programs, providing both facilities and training opportunities for academic and professional development in observational techniques. Leveraging advanced orbital data processing techniques, the observatory has developed innovative platforms to streamline observation planning, thereby maximizing its contributions to the scientific objectives outlined by the IAU-CPS center. In this contribution, we highlight the progress made by the Observatory team and the facilities available to observatories worldwide, fostering a collaborative environment for advancing satellite observation and data analysis programs.

An environmental approach to protect the dark and quiet skies for astronomy and society

Mr Pedro Sanhueza

Ministry of Foreign Affairs, Chile

Abstract

The impact on optical and radio astronomy from satellite constellations has been systematically studied in recent years. These adverse effects are highly relevant, posing a risk to the continuation of astronomical activities conducted from Earth. However, the proliferation of satellites in orbit and the re-entry of such satellites and space debris is currently affecting the natural darkness of the night sky and can also affect the stratospheric ozone layer and compromise the radiative balance of this layer. The metals produced by satellite particles burning upon re-entry into the atmosphere disperse throughout the stratosphere, potentially contributing to the destruction of portions of the ozone layer through chemical reactionsThese environmental effects are currently unpredictable, though potentially very serious. It is urgent to study these effects and apply the preventive environmental principle to regulate the proliferation of satellite constellations based on current indications of possible damage, even though there is still no certainty about these environmental harms, which are already evident to astronomical science. This approach will safeguard the stratospheric ozone layer and protect astronomical science, providing a stable and predictable scenario for satellite operators to conduct their activities.

A study on the periodic orbits in the Copenhagen problem with non spherical primaries

Dr. Om Prakash Meena

Hans Raj College, University of Delhi

Abstract

In this paper, we have drawn the periodic orbits in the Copenhagen problem. The test particle of infinitesimal mass moves under the Newtonian gravitational law due to two mass points with constant angular velocity. We have studied the dynamics of the third body in the Copenhagen problem with non-spherical primaries. We have determined the periodic orbits by using the Fourier series method around the libration points. The effects of the orbital parameter ε ($0 < \varepsilon < 1$), which controls the size of the orbit, on the periodic orbits and their period are investigated. In order to study the effect of this parameter, we have retained the terms up to third order with respect to the orbital dimensions. We have unveiled that how oblateness influence the shape, size, and period of the periodic orbits.

Study on the Angular Distance between Celestial Bodies in Korean Astronomical Records during the 11-18th Centuries

Ph.D Student Hyojun Lee[1,2,3], Dr. Hong-Jin Yang[2,4], Prof. Suk-Jin Yoon[3], Prof. Myeong-Gu Park[5]

[1]Korea National University of Science and Technology (UST). [2]Korea Astronomy and Space Science Institute (KASI). [3]Department of Astronomy, Yonsei University. [4]Korea Natioanl University of Science and Technology (UST). [5]Department of Astronomy and Atmospheric Sciences, Kyungpook National University

Abstract

There remain numerous astronomical observations such as eclipses, comets, SNe, close approaches, etc. in Korean chronicles. Records of close approaches between celestial objects use specific terms to describe the angular distance. We study five commonly used terms, namely, *Entry* (*En*), *Invasion* (*In*), *Occultation* (*Oc*), *Eclipse* (*Ec*), and the unit *Chi*. We analyze over 2,300 records from the Goryeo (918-1392 CE) and Joseon (1392-1910 CE) Dynasties. We convert the lunisolar calendar to the Julian and Gregorian date and utilize ephemeris DE431 to calculate the angular distance. By finding the closest angular distances for all records, we determine their quantitative definitions through statistical analysis. We find that the angular distances of the four terms are in the range of 1-6 times the Moon's radius. The terms *En*, *In*, *Oc*, and *Ec* represent decreasing angular distance in that order and this ordering was consistent in both dynasties. To examine the angular size of the unit *Chi*, we additionally use the comet drawings in 1664-1665 and find that 1 *Chi* corresponds to ~1.11°. Furthermore, we investigate the correlation between the angular distance and planets' apparent magnitude.

[4]School of Environmental and Chemical Engineering, Shanghai University, Shanghai 200444, China

Abstract

With the application promotion of space geodesy, the popularization of remote sensing technology and the development of artificial intelligence, a more accurate and stable Terrestrial Reference Frame (TRF) has become more and more urgent. For example, sea level change detection, crustal deformation monitoring, driverless and so on require the accuracy of the terrestrial reference frame to be better than 1 mm in positioning and 0.1 mm/a in velocity respectively. However, the current frequently used ITRF2014 and ITRF2020 don't satisfy such requirements. Therefore, this paper study and reveal that there are time-dependent periodic signals especially in the GNSS coordinate residual data, which can lead to incorrect estimation of the station coordinates and velocities, further affecting the accuracy and stability of the TRF. These nonlinear periodic signals could be modeled well by the Singular Spectrum Analysis (SSA). After SSA corrections the re-calculate the TRF and the consistent EOP, based on the Chinese Earth Rotation and Reference System Service (CERS) Terrestrial Reference Frame (TRF) and Earth Orientation Parameters (EOP) determination software package (CERS TRF&EOP) developed by the Shanghai Astronomical Observatory (SHAO) (He et al., 2017) could be obtained. Then their accuracy could be evaluated corresponding to ITRF2014 or ITRF2020 and IERS 14 C04 or IERS 20 C04, respectively. The results show that the accuracy and stability of the newly established nonlinear terrestrial reference frame and EOP have been greatly improved and better than linear TRF.

The prospection of an astronomical site to build the first USMS university observatory

Saadia Oujaoura

Faculty of Sciences and Techniques of Beni Mellal, Morocco

Abstract

We present a preliminary astroclimatical study of the Tassemit site. It is located in the Middle Atlas Mountains of Beni Mellal, Morocco, (2204m a.b.s, 32°18'00" N and 6°15'00" W). This site is no far from Sultan Moulay Slimane Campus. Tassemit is easily accessible by a good road, and not affeted by the Beni Mellal city light pollution.

Our research focused on evaluating Tassemit's astronomical potential, comparing its calculated seeing using satellite data with the ORM site's in situ measurements. The results unveiled remarkably good seeing conditions at Tassemit, affirming its suitability as an optimal astronomical observation site with pristine skies and minimal atmospheric interference.

Gravimetric excitation of polar motion from SLR+GRACE/GRACE-FO hybrid solutions

professor Jolantaa Nastula[1], dr Justyna Śliwińska-Bronowicz[2], dr Małgorzata Wińska[3]

[1]Centrum Badań Kosmicznych PAN (Space Research Centre PAS). [2]Centrum Badań Kosmicznych PAN (Space Research Centre PAS). [3]Faculty of Civil Engineering, Warsaw University of Technology, Warsaw, Poland

Abstract

The Earth's rotational motion is highly complex, and currently, no comprehensive analytical model exists for it. Temporal variations in this motion are influenced by various geophysical phenomena, including changes in mass distribution within the atmosphere, oceans, hydrosphere, and cryosphere.

The GRACE and GRACE-FO missions have provided essential data to comprehend the time-variable gravity field resulting from global mass distribution changes. The changes in the degree-2 order-1 coefficients of geopotential (C21, S21) are proportional to changes in the equatorial components of PM excitation.

However, limitations in GRACE/GRACE-FO solutions, particularly in determining geopotential coefficients of lower degrees, have been identified.

We use time-variable gravity solutions obtained from a combination of GRACE/GRACE-FO data and Satellite Laser Ranging (SLR) observations from Institut für Geodäsie und Geoinformation, Universität Bonn (IGG) and Centre National D'Etudes Spatiales (CNES) to calculate Hydrological Angular Momentum (HAM). We assess the HAM series by comparing them with the hydrological signal in observed PM excitation, known as geodetic residuals (or GAO), focusing on both seasonal and non-seasonal variations.

The results are promising and demonstrate high agreement between HAM obtained from SLR+GRACE/GRACE-FO and the GAO. Our findings indicate that the excitation functions derived from the hybrid solution closely align with the GAO. In fact, they exhibit similar or even better consistency with the GAO than the series derived from single GRACE/GRACE-FO solutions. Worth noting is the high correlation (at the level of 0.8) and variance agreement (up to 80%) observed in the long-term part of the spectrum.

Calculating the trajectory of a gram-scale interstellar spacecraft moving at relativistic speeds

Mr. Nicky Ishaak[1], Dr. Mark C. Baumann[2], Dr. Justin C. Feng[3]

[1]The University of Texas at Dallas. [2]St. Edward's University. [3]Leung Center for Cosmology and Particle Astrophysics, National Taiwan University,

Abstract

PoMiN is a relativistic N-body gravitational dynamics solver that uses a Post-Minkowski approximation to general relativity (GR) and is accurate at ultra-relativistic speeds. It was originally written in the C language, but recently has been ported to the Julia language. An application of interest for PoMiN is the computation of trajectories of relativistic spacecraft, such as those proposed by the Breakthrough Starshot Initiative. The goal of the Breakthrough Starshot Initiative is to develop an interstellar spacecraft capable of traveling to the nearest star in less than a human lifetime. It proposes building a gram-scale spacecraft that is attached to a light sail and accelerated to 0.2c, either by a ground- or spaced-based laser array. The spacecraft is microchip-sized and equipped with miniaturized sensors and communications. It would have minimal propulsion of its own; therefore, after the initial acceleration, it would be left to make the 20-year trek to Proxima Centauri, approximately 4.25 light years away, with minimal course corrections. The question to be answered is: how can the trajectory of the spacecraft be computed? To compute the trajectory of the spacecraft involves accounting for gravitational dynamics between many bodies, for example, the Sun, Earth, Moon, other planets in our solar system, Alpha Centauri A and B, Proxima Centauri, and the spacecraft itself. To begin the investigation, a set of initial data was created. Online astronomical databases were used to obtain orbital elements, masses, and accurate positions and velocities. This presentation will discuss the initial conditions, detailed results, challenges and implications.

Mass measurement of a Local group dwarf spheroidal galaxy using Gaia EDR3

Dr Zolile Mguda

University of South Africa

Abstract

Dwarf spheroidals (dSph) are dense spherical galaxies with high mass-to-light ratios. They vary greatly in mass, star formation history and dynamical properties. The proper motions of stars in almost all the Milky Way DSphs can be resolved in Gaia EDR3 data. This allows for the measurement of the dynamics of the dSph galaxies and thus allows us to probe the mass-to-light ratios of these galaxies using 2-dimensional velocity measurement instead of 1-dimensional line-of-sight velocities, as used in the virial theorem.

In this study we use the Leonard-Merritt method to measure the masses of one of the Milky Way Galaxy satellites. The mass distribution is modeled by fitting the photometric characteristics of the dwarf galaxy to the King model. The gravitational potential is modeled using the proper motion data from the GAIA space telescope. This allows us to measure the masses of some of our closest dwarf spheroidal galaxies using a single data set and one mass measurement technique. this is an important step in the study of the dark matter content of galaxies in the Local group and the search for intermediate mass black holes. The dSph galaxies provide an intermediate arena between the dynamics of massive elliptical galaxies and globular clusters. This allows us to probe the formation scenarios of the MW globular clusters as in-situ formation or galaxy infall.

A new post-Newtonian long-term precession model for the Earth

Kai Tang[1], Michael Soffel[2], Jin-He Tao[1], Zheng-Hong Tang[1]

[1]Shanghai Astronomical Observatory, Chinese Academy of Sciences. [2]Lohrmann Observatory, Dresden Technical University

Abstract

Long-term precession represents the secular motion of the Earth's axis for a long time interval. In 2015, we calculated the Earth's long-term precession in a relativistic framework. However, our previous works involving the ecliptic in the Geocentric Celestial Reference System are deficient, because the natural definition of this ecliptic is still ambiguous. To obtain a long-term precession model in accordance with general relativity, improvements are made including the following: all calculations are no longer carried out in the reference related to any ecliptic; a new hybrid integrator is designed and used for this precession model; ecliptic-independent precession parameters are calculated and provided. A detailed comparison analysis is performed to estimate the importance of various relativistic influences on the precession parameters. Valid within the interval of ±1 Myr around J2000.0, a consistent post-Newtonian long-term precession model for the Earth has been achieved and is presented here.

Comparative Analysis of the Parameters of Pulsars with Breaking Indices n<0 and n>0

Dr Chika Onuchukwu

Chukwuemeka Odumegwu Ojukwu University

Abstract

We analyzed the timing parameters (the rotational frequency, the first and second time-derivatives of frequency) and the derived parameters of a sample of pulsars for which second time-derivatives of frequency (470 pulsars) were recorded in the Australian Telescope National Facility (ATNF) pulsar catalog. We formed various subsamples, those with breaking indices n<0 and n>0 , and glitching and non-glitching pulsars. Our statistical analyses of the timing and derived parameters indicated some level of differences and similarities in the parameters analyzed. Glitching pulsars appear to a have higher rotational frequency than non-glitching pulsars, and pulsars with n>0 appear to rotate faster than those with n<0 . Our results also suggest that glitching pulsars have lower values of |n| (where |n| is the absolute value of breaking index), and is it lower for subsample with n>0 than for subsample with n<0.

Study of the small body dynamics with variable mass in the presence of reactive forces in the framework of the restricted three-body problem with variable masses

Aigerim Ibraimova[1,2], Mukhtar Minglibayev[2], Alexander Prokopenya[3]

[1]Fesenkov Astrophysical Institute. [2]Al-Farabi Kazakh National University. [3]Warsaw University of Life Sciences

Abstract

Among the actual problems of modern astronomy is the question of the origin and evolution of small bodies in planetary systems.

The goal of our work is to investigate the secular perturbations of a restricted three-body problem with masses varying at different rates. The masses of the bodies change non-isotropically and there occur reactive forces. The motion equations of the bodies are described in a relative coordinate system with the origin at the center of the most massive body. The problem was investigated by methods of perturbation theory [1] on the basis of aperiodic motion along a quasiconical section developed for non-stationary gravitating systems.

We obtained the differential equations of perturbed motion in the osculating elements of aperiodic motion along quasiconical section. In the non-resonant case, we obtained evolution equations that determine the orbital element changes in large time intervals [2].

The obtained evolution equations are applied to the non-stationary restricted three-body problem (Sun-Jupiter-Asteroid) and investigated by numerical methods.

This research was funded by the Committee of Science of the Ministry of Science and Higher Education of the Republic of Kazakhstan (Grant No. AP14869472).

Exploring the impact of a priori errors on dUT1 estimations from intensive VLBI sessions

Clara Pérez[1], Santiago Belda[2], Esther Azcue[1], Maria Karbon[2]

[1]National Geographic Institute of Spain, Madrid, Spain. [2]UAVAC, Applied Mathematics Dept., University of Alicante, Alicante, Spain

Abstract

One of the primary objectives of very long baseline interferometry (VLBI) is to obtain accurate Earth orientation parameters (EOP), which play a crucial role in geodesy, space navigation and adjacent sciences. In particular, VLBI is the only technique capable of independently determining dUT1, the difference between the Universal Time (UT1, based on the Earth's phase of rotation) and Coordinated Universal Time (UTC, based on atomic clocks). For this purpose, intensive 1-hour VLBI sessions are conducted daily, usually involving up to three antennas. The limited observation time of 1 hour, compared to the 24 hours usually reserved for EOP determination, along with a minimal station network configuration, only allows for the determination of the EOP associated with the UT1-UTC difference (dUT1). The remaining EOP parameters are fixed at their a priori values, thereby making the precision of this parameter significantly reliant on the a priori data.

We aim to deepen our comprehension of how errors in a priori information influence the determination of dUT1. Our approach involves systematically introducing variations in key parameters to quantify their impact on resulting dUT1 estimations. The overall sensitivity of this parameter to different sources of error is analyzed leveraging real data from intensive sessions published by the International VLBI Service (IVS).

Improving the geodetic budget closure by combining geophysical excitations of polar motion from different models of atmospheric and oceanic angular momentum

Dr Justyna Śliwińska-Bronowicz[1], Dr Małgorzata Wińska[2], Prof. Jolanta Nastula[1]

[1]Centrum Badań Kosmicznych Polskiej Akademii Nauk (CBK PAN). [2]Faculty of Civil Engineering, Warsaw University of Technology,

Abstract

Processes occurring within the Earth's system continually alter the distribution of mass within geophysical fluids, including the atmosphere, ocean, and land hydrology, consequently influencing the Earth's rotation. The mass redistribution and its movements within the Earth system excite the Earth's rotational changes at different time scales. The significance of atmospheric and oceanic angular momentum (AAM and OAM, respectively) signals in polar motion (PM) excitation on seasonal and interannual timescales is well recognized. Nonetheless, variations exist among various estimates of AAM and OAM obtained from different geophysical models. Despite the smaller impact on PM, taking into account hydrological angular momentum (HAM) is important in closing the geodetic budget, i.e. achieving full agreement between AAM+OAM+HAM and the observed geodetic angular momentum (GAM).

The aim of this study is to demonstrate the potential extent of differences among diverse AAM and OAM representations derived from various models. We intend to show that using different combinations of mass and motion terms of AAM and OAM may considerably influence in the correspondence with GAM. We also present a combined time series of AAM and OAM computed using the three-cornered hat (TCH) method, in which the internal noise level is reduced to a minimum, and compare them with the GAM. Additionally, we present the level of consistency between the sum of AAM+OAM+HAM and GAM. This analysis could indicate whether exploiting such a combination calculated with TCH method, with representation of HAM added, can lower the errors in the geodetic budget closure.

An updated value of the dynamical ellipticity of the Earth

Alberto Escapa[1], Tomás Baenas[2], José Manuel Ferrándiz[3]

[1]Department of Aerospace Engineering, University of León, 24071 León, Spain. [2]Department of Sciences, University Centre of Defence at the Spanish Air Force Academy, 30720 Santiago de la Ribera, Spain. [3]Department of Applied Mathematics, University of Alicante, 03690 Alicante, Spain

Abstract

The current value of the dynamical ellipticity of the Earth *H* comes from International Astronomical Union (IAU) precession model —IAU2006 precession— derived in Capitaine et al. (2003). That value is also considered in the International Earth Rotation and Reference System Service (IERS) numerical standards, which are described in chapter 1 of IERS Conventions (2010).

To update *H* we follow the same procedure as in Souchay & Kinoshita (1996) —also in Williams (1994) and Capitaine et al. (2003). It is based on determining *H* from the numerical value of the general precession in longitude, which is expressed as a part proportional to *H* —first order lunisolar precession— plus second order contributions.

Specifically, we enhance the modeling of second order contributions with the help of the Hamiltonian formalism. First, we introduce the terms arising from a perturbation theory at the second order, absent in IAU 2006, for the non-rigid Earth (Baenas et al. 2017). Second, we incorporate the contributions due to the redistribution of mass of tidal origin in a clear and systematic way. Their values are computed from Love sets from IERS Conventions (2010, chapter 6) and Williams & Boggs' (2016) direct oceanic tides.

Such systematic approach allows us, in contrast to other astronomical studies, indicating the tidal system that is used for giving *H*. In particular, we recommend H to be provided in the zero-frequency convention (Escapa et al. 2022, 2023). This policy is necessary to get a consistent system of numerical constants as such used in Astrodynamics, Astronomy, Geodesy, etc.

Analysis of Tropospheric Delay Mapping Functions with co-located WVRs on VLBI Stations

Ms Weili Zhou, Professer Shuli Song, Dr Jun Jiang

Shanghai Astronomical Observatory, Chinese Academy of Sciences

Abstract

Tropospheric delay is one of the major error sources for the high-accuracy Very Long Baseline Interferometry (VLBI) technique due to the rapid water vapor variation. Over the past years, Niell mapping function (NMF) and Global Mapping Function (GMF) are commonly devised aiming at mapping the delay of radio waves from the zenith direction down to the observational direction in real-time deep space exploration. China's VLBI measurement and control network includes 4 radio telescope stations located in Shanghai, Kunming, Urumqi, and Beijing and a VLBI data processing center located in Shanghai, which is used to observe and determine spacecraft trajectory. Therefore, we validate the accuracy of different Real-time Mapping Functions (RMFs) on VLBI signal corrections, based on postprocessing Vienna Mapping Function 3 (VMF3) and Water Vapor Radiometers (WVRs) applied to track Tianwen-1 spacecraft simultaneously. Meanwhile, the accuracy of different RMFs at low elevation angle intervals (1°-30°) are analyzed compared with VMF3 at China's VLBI stations. Comparisons of tropospheric delay quantitatively demonstrate that Global Pressure and Temperature 3 (GPT3) is slightly better than NMF and GMF overall, which belongs to RMFs. This study can provide a reference for tropospheric delay calibration of the spacecraft or other radio observations using VLBI technique, especially at low elevation angles.

Cryospheric Excitation on the Earth's Chandler Wobble

Mr. Cancan Xu[1,2], Qiqi Shi[1,2], Chengli Huang[3,2], Yonghong Zhou[3,2]

[1]Shanghai Astronomical Observatory, Chinese Academy of Sciences, Shanghai 200030, China. [2]School of Astronomy and Space Science, University of Chinese Academy of Sciences, Beijing 100049, China. [3]CAS Key Laboratory of Planetary Sciences, Shanghai Astronomical Observatory, Chinese Academy of Sciences, Shanghai 200030, China

Abstract

Leveraging GRACE mascon products during 2002 and 2023, we for the first time ascertain the substantial influence of mass variations in cryosphere on the Earth's Chandler wobble (CW). In addition, in contrast to traditional analysis conducted in the excitation domain, our study focuses on the polar motion domain and incorporates the wavelet analysis technique. The findings reveal some intriguing phenomena: between 2006 to 2020, the cryosphere contributed an average amplitude of approximately 4.85 mas to CW, equivalent to 5.05%, with its impact escalating to about 11 mas from 2018 to 2022, representing a fourfold rise in its contribution ratio to approximately 20%. This marked surge can be attributed to more erratic glacier mass balance resulting from ongoing climate change. Moreover, there is a pronounced decrease in the CW signal post-2018, which starkly contrasts with cryospheric contribution, suggests a potential linkage to climate change yet warrants further investigation.

Origins of the intradecadal oscillations in length-of-day and implications

Dr. Pengshuo Duan[1], Chengli Huang[1,2]

[1]CAS Key Laboratory of Planetary Sciences, Shanghai Astronomical Observatory, Chinese Academy of Sciences, Shanghai 200030, China. [2]School of Astronomy and Space Science, University of Chinese Academy of Sciences, Beijing 100049, China

Abstract

Variations in Earth rotation rate defined by length-of-day (LOD) on the intradecadal scales present two primary periodic (i.e., 6yr and 8.6yr) oscillations, the specific physical mechanisms responsible for them (especially the 8.6yr oscillation) are still less clear. Using the latest core surface flow data inferred from the modern continuous satellite magnetic observations for 1999-2021, we calculate the electromagnetic torque exerting on the mantle, where two obviously periodic (i.e., 6yr and 8.6yr) components are detected and accurately extracted in time domain to present the existence of the core waves with the same periods. Based on the predicted LOD change data from the previously geostrophic core flow model for 1962-2021, this work supports that the observed 6yr LOD oscillation mainly reflects the signatures of geostrophic torsional waves, while the 8.6yr LOD oscillation cannot be interpreted by these waves. In order to explore the origin of 8.6yr oscillation, we develop the LOD change model due to the quasi-geostrophic Magneto-Coriolis (QG-MC) waves, which relates to the azimuthal core surface flow data. Our results suggest that the eastward propagating QG-MC waves can give a good interpretation of the 8.6yr LOD oscillation (including the amplitude and phase), providing the strong evidence to exhibit that 6yr and 8.6yr LOD variations originate from the different core wave mechanisms. This work is significant to understand the fast dynamics of the core-mantle system.

THE ASTROPHYSICAL DYNAMICS AND EARTH'S CLIMATE CHANGE

Mr Kaguamba Minjire

University of Nairobi

Abstract

The Earth's climatic changes are mainly attributed to artificial causes such as deforestation, carbon emissions from use of fossil fuels and other greenhouse gases. However, a few studies (Haigh J. 2011) have pointed towards a possible astrophysical and outer space contribution to the Earth's climate change, which requires further investigation given the significance of this problem to the future existence and sustainability of life on our planet Earth. Interactions between energy from the Sun, the Earth, and the atmosphere contribute to what is known as the global energy balance. Solar output is characterized by changes which can alter the energy balance. This can play a role in regulating the Earth's climate. Scientists (see e.g. Seitz 1996) have disagreed with the popular notion of attributing climatic changes to human causes. The main intent of this research work is to comprehend the role of solar activity and any probable astrophysical interactions in altering the Earth's climate. This will be achieved by modeling the manner in which solar radiation interacts with the Earth's atmospheric layers. We utilize data from various institutions that deal with climate change, and theoretical framework from the scientific disciplines that encompass climate science such as space physics, solar physics, atmospheric physics and astrophysics. The Earth's climate will be examined during the periodic variations of the Sun and establish the effect of the varying solar irradiance on the global energy balance. Occasional changes in the environment influenced by celestial objects present between the Earth and the Sun will be studied extensively in this research.

Development of lunar ephemeris with an Earth tide model compatible to the IERS conventions

Dr Wei Tian

Shanghai Astronomical Observatory, Chinese Academy of Science

Abstract

Earth tide plays important roles in the development of modern planetary and lunar ephemeris. At present, several Earth tide models used by ephemeris groups differ to each other at the detectable level and are not fully consistent with the one recommended by the International Earth Rotation and Reference Systems Service (IERS) conventions (2010). This work aims to investigate impacts of different Earth tide models on the development of planetary and lunar ephemeris, especially on fitted results of dynamical parameters of the Earth-Moon system. With accumulated high-precision lunar laser ranging (LLR) measurements and updated planetary measurements, a new version of planetary and lunar ephemeris is built, meanwhile, sensitivity of several dynamic parameters of the Earth-Moon system to the adopted earth tide models is investigated.

Investigating Merger-Induced Asymmetries in HI Spectra of Nearby Galaxies: A Full ALFALFA Sample Analysis

MISS YANDISA PEKO

UNIVERSITY OF THE WESTERN CAPE

Abstract

This project will examine the properties of the environments in which these galaxies reside by utilizing optical counterparts cross-matched with ALFALFA galaxies. Leveraging Data Release 15 of the Sloan Digital Sky Survey (SDSS), environmental densities and other properties will be determined. The main scientific question is: What evidence does the full ALFALFA sample offer for merger-induced asymmetries in the HI spectra of galaxies in the nearby Universe? The global HI profile, representing the frequency distribution of spatially integrated HI content, contains valuable information about a galaxy's rotational properties and HI distribution. Any observed asymmetries in an isolated galaxy's HI profile are typically attributed to recent merger activity. Traditionally, optical observations have been employed to study merger activity, but detecting and quantifying interactions solely through stellar disks can be challenging due to their small and densely distributed nature. Late-type galaxies, however, also contain substantial amounts of neutral atomic hydrogen (HI), distributed in a rotationally-supported disk extending beyond the stellar disk. The disturbed HI morphology is a durable tracer of a galaxy's interaction history.

The Milky Way as Einstein's paradigm in the Gaia era

Dr Mariateresa Crosta[1], William Beordo[1,2], Dr Mario Gilberto Lattanzi[1], Dr Paola Re Fiorentin[1], Dr Alessandro Spagna[1]

[1]INAF-OATo. [2]University of Turin, Physics Dept.

Abstract

General astrometric relativistic models matched with Gaia data offer the unique possibility of establishing a multi-laboratory for extensively testing gravity theories and the Milky Way kinematic/dynamics, in other words a coherent frame to probe our whole Galaxy as the product of cosmological evolution shaped by gravity (Local Cosmology), i.e. the relations among baryonic structures (and their evolution) and the dark components of the Universe.

The presentation will focus on the latest results on the Milky Way rotational curve as obtained by comparing an exact general relativistic approach with the (Λ)CDM and MOND, namely un update with Gaia DR3 on what was first obtained with Gaia DR2 (https://www.cosmos.esa.int/web/gaia/iow_20200716). Furthermore, it will be evidenced how some selected "geometries" of the Galaxy can play a reference role for other galaxies, just like the Sun for star models.

Proposed Grid System and Projected Coordinate Reference Systems for Lunar Surface Navigation and The Artemis Missions

Geodesist Mark McCleran

United States Geological Survey

Abstract

Artemis is a milestone in human space exploration. It is the first project to return astronauts to the Moon since 1972. Fundamentally the success of each Artemis Mission will be based on the ability to navigate. To date, a navigational standard has not been developed for lunar surface navigation.

The Artemis Geospatial Data Team has tasked USGS Astrogeology to develop a grid and associated projected coordinate reference systems optimized for lunar navigation. The Data Team has specified the PCRS must have a specified map scale error and the grid must be high precision utilizing a limited number of coordinate characters.

USGS is assessing the feasibility of a PCRS for surface operations. We propose developing a new Lunar Transverse Mercator (LTM), the Lunar Polar Stereographic (LPS), and the Lunar Grid Reference Systems (LGRS)[1]. We have also embedded additional grids designed to NASA requirements for astronaut navigation, referred to as Artemis Condensed Coordinates (ACC) [1].

LTM, LPS, and LGRS are similar in design and use to the Universal Transverse Mercator (UTM), Universal Polar Stereographic (LPS), and Military Grid Reference System (MGRS)[2]; but adhere to NASA requirements [3]. LGRS ACC format is similar in design to Apollo orthotopophoto charts for navigation [4].

PCRSs and grids are subject to change based on results from field testing by the Joint EVA Test Team, NASA, and USGS [3].

New paradigm of close approach analysis of NEOs: likelihood of close encounter

Dr. Dmitrii Vavilov, Dr. Daniel Hestroffer

IMCCE, Observatoire de Paris

Abstract

For a large set of asteroids – in particular newly discovered NEAs – the precise orbits are unknown. The area of possible positions of an asteroid (uncertainty region) can be large, and even reach the whole revolution around the Sun, while being extremely thin and stretched mostly along the nominal orbit of an asteroid. Because of that, the close approach data of asteroids is generally incomplete. On the other hand, a nominal position of an asteroid can be far from the Earth, but at the same time the asteroid can actually have a close approach or even collide with the Earth. This is one of the reasons why different centers for asteroid dynamics study (Minor Planet Center, Jet Propulsion Laboratory NASA, IMCCE,…) publish different results for asteroids close approach data: They have different nominal solutions that lead to difference in outcome.

In this work we propose the paradigm of assessing the probability that an asteroid comes closer to the Earth on a certain distance (0.05 au) rather than publishing the close approach information for only the nominal solution. We assume that the errors of coordinates of a special curvilinear coordinate system have Gaussian distribution during the whole period of consideration (this Century). This assumption is quite reasonable and allows us to take into account the fact that uncertainty region looks like a thin curvilinear ellipsoid stretched mostly along the nominal asteroid's orbit. We made some modifications to the 'Partial Banana Mapping' method to compute the required information.

Numerical Standards for Fundamental Astronomy Current Best Estimates

Dr Susan Stewart

US Naval Observatory

Abstract

IAU Division A Commission A3 (CA3) on Fundamental Standards continues to fill an important and necessary role in the IAU and wider astronomical research community by identifying, researching, coordinating and communicating fundamental astronomical standards. IAU Resolution B2 in 2009 recommended that the IAU establish a permanent body to maintain the Numerical Standards for Fundamental Astronomy (NSFA) Working Group's list of Current Best Estimates (CBE). One of the CA3's first tasks was to take over responsibility for the upkeep of CBE list, which is now hosted on the CA3 website: https://iau-a3.gitlab.io/. The CBE gives both constants fixed by convention as well as those which are measurable and determined by currently available research. The CA3 has updated those constants which current research produces better values. We will present updates to the CBE list which include new standard masses for several solar system planets and planetary satellites.

The Cartographic Lunar Reference Frame

Dr. Brent Archinal

Astrogeology Science Center, U. S. Geological Survey

Abstract

Two different coordinate systems have long been in use for the Moon. These are the Mean Earth/polar axis (ME) and the Principal Axis (PA) systems. ME is defined by having 0° longitude in the mean direction of the Earth and an equator defined by the mean direction of the lunar pole, whereas PA is defined by the axes of the principal moments of inertia. The IAU Working Group on Cartographic Coordinates and Rotational Elements (WG) previously has recommended the use of the JPL DE421 ephemeris, rotated to an ME frame for defining lunar coordinates (https://doi.org/10.1007/s10569-017-9805-5).

Over the last 3 years both the Artemis III SDT report https://www.nasa.gov/wp-content/uploads/2015/01/artemis-iii-science-definition-report-12042020c.pdf) and the LEAG-MAPSIT LCDP SAT report (https://www.lpi.usra.edu/mapsit/reports/leag_mapsit_report_2022-01-11.pdf) have included recommendations for an updated frame. Park et al. (https://iopscience.iop.org/article/10.3847/1538-3881/abd414) have published new Solar System ephemeris results that include a lunar laser ranging solution and lunar orientation ephemerides. The latter includes the DE440 ephemeris in the ME frame, which is compatible with their earlier DE421 ME frame recommended for use by the WG. The WG is considering and accepting input on whether this new frame and ephemeris should be recommended for lunar cartographic use.

There has been some recent discussion that a PA-based frame should be used for mapping instead. That would be a major change to how lunar data are currently acquired, and how data and mapping products are created and archived, searched for, accessed, and used. The benefits of such a change are not apparent.

Special Configurations of PlanetsIn Section A of the Astronomical Almanac, phenomena are listed forthe year under consideration. This includes both geocentric and heliocentricphenomena. The conjunctions of one planet with another are defined as the timewhen the difference of the right ascensions of the two planets is zero. At thistime the difference in the declinations will be the separation between theplanets in the sky.When we come to considering configurations of three planets in the night sky,two situations are frequently sought: times when they appear closest to eachother and when they appear aligned. A more precise definition of these can be,when the three planets are contained in the circle with smallest diameter andif they are aligned and so lie on the same great circle of the celestialsphere. In the book Astronomical Algorithms by Meeus (1991) he addressed theseproblems. So although these configurations cannot be defined as precisely asclassical astronomical phenomena they may still be of interest to observers ofthe night sky.Two special configurations involving three planets are considered: (i) agrouping with the diameter of the smallest circle containing the bodies,(ii) analignment on a great circle of the celestial sphere. Dates for suchconfigurations were found with only the planetsvisible with the naked eye considered. Preliminary analysis showed nearperiodicity in time interval in some sequences of dates of (i), and for (ii)occurrences of different alignments on the same date.

Dr. Steven Bell, Dr. Donald Taylor

HMNAO, UK Hydrographic Office

Abstract

Special Configurations of Planets

In Section A of the Astronomical Almanac, phenomena are listed for

the year under consideration. This includes both geocentric and heliocentric

phenomena. The conjunctions of one planet with another are defined as the time

when the difference of the right ascensions of the two planets is zero. At this

time the difference in the declinations will be the separation between the planets in the sky.

When we come to considering configurations of three planets in the night sky, two situations are frequently sought: times when they appear closest to each other and when they appear aligned. A more precise definition of these can be, when the three planets are contained in the circle with smallest diameter and if they are aligned and so lie on the same great circle of the celestial sphere. In the book Astronomical Algorithms by Meeus (1991) he addressed these problems. So although these configurations cannot be defined as precisely as classical astronomical phenomena they may still be of interest to observers of the night sky.

Two special configurations involving three planets are considered: (i) a grouping with the diameter of the smallest circle containing the bodies,(ii) an alignment on a great circle of the celestial sphere. Dates for such configurations were found with only the planets visible with the naked eye considered. Preliminary analysis showed near periodicity in time interval in some sequences of dates of (i), and for (ii) occurrences of different alignments on the same date.

Central configurations in the general four body coplanar problem with different masses

Dr Muhammad Shoaib[1], Dr Brahim Benhammouda[2], Professor Bonnie Steves[3], Dr Winston Sweatman[4]

[1]Smart and Scientific Solutions, 32 Allerdyce Drive, Glasgow, G15 6RY. [2]Higher Colleges of Technology, United Arab Emirates. [3]Glasgow Caledonian University, Glasgow, G4 0BA, Scotland, UK. [4]School of Mathematical and Computational Sciences, Massey University, Private Bag 102 904, Auckland 0745, New Zealand

Abstract

The research described in this paper, solves the outstanding problem of finding central configurations in the general four body coplanar problem for four different masses, with no need for symmetrical restrictions.

We have used a novel approach where three masses are distributed on the vertices of a triangle, with the fourth mass allowed to be at any other point in the plane forming either convex or concave central configurations. A necessary condition is derived for the existence of central configurations and for requiring the masses to be positive. Using both analytical and numerical techniques, regions of possible central configurations can be derived.

We have identified new non-symmetric different mass central configuration solutions in the four body coplanar problem. And we have shown that through using our general four body coplanar model for central configurations, we can replicate all the known symmetrical four body non-collinear central configurations. The cases derived include: the isosceles trapezoid, the right trapezoid, the convex kite, the concave kite, the right quadrilateral and a number of cases both convex and concave with no symmetry restrictions or equality of masses. Various cases are also identified where no central configurations are possible.

UKIRT Hemisphere Survey Status, Details and Data Access

Justice Bruursema[1], Frederick Vrba[1], Jeffrey Munn[1], Michael Irwin[2], Andy Lawrence[3], Watson Varicatt[4], Klaus Hodapp[5], Tom Kerr[4], Mike Read[3]

[1]United States Naval Observatory. [2]Institute of Astronomy, University of Cambridge. [3]Royal Observatory, Edinburgh. [4]United Kingdom Infrared Telescope. [5]Univeristy of Hawaii

Abstract

We present details and the current status of the United States Naval Observatory (USNO)-led continuation of the UKIRT Hemisphere Survey (UHS) program. The UHS was originally begun in 2012 by a United Kingdom (UK)-based collaboration with the United Kingdom InfraRed Telescope (UKIRT) in the J band. The goal was to fill in all areas of the northern celestial hemisphere with latitudes from $\delta=0^{\circ}$ to 60° that were not already observed in the UKIRT Infrared Deep Sky Surveys (UKIDSS) program. The UHS, together with UKIDSS, provides imaging that has a substantially improved depth and finer PSF than 2MASS data and provides a next-generation all-sky infrared map when combined with complementary VISTA Hemisphere Survey (VHS) data for the southern hemisphere. The J band data were released in 2018 and at that time, USNO took the lead in continuing the UHS project in the K band, in collaboration with UK and University of Hawaii (UH) partners. The K band data (both imaging and source catalogs) were released in 2023 and are available through the WFCAM Science Archive (WSA) from the Royal Observatory, Edinburgh, along with the other relevant UKIRT data. The H band data should be publicly available in early 2025. We have also begun a second epoch of J band observations with simultaneous Y band imaging that will be available in the future. The poster presented here will orient you to the parameters and details of the surveys and how to access the data.

Rubin's LSST as an astrometric and a photometric survey

Zeljko Ivezic

AURA/University of Washington and the Rubin Observatory Team

Abstract

The Legacy Survey of Space and Time (LSST), the first project to be undertaken at the new Vera C. Rubin Observatory, will be the most comprehensive optical astronomical sky survey ever undertaken. Starting in 2025, Rubin Observatory will obtain panoramic images in ugrizy passbands covering the sky visible from its location in Chile every clear night for ten years, resulting in close to a thousand observations of each position across half of the celestial sphere. About 20 billion galaxies and a similar number of stars will be detected using this 60 petabyte image dataset. LSST data will be used for investigations ranging from cataloging potentially hazardous near-Earth asteroids, to stellar and black hole astrophysics, and fundamental physics such as the characterization of dark matter and dark energy. I will briefly overview scientific goals behind this project, provide a construction status update, and finish with a discussion of astrometric and photometric accuracy expected for LSST.

Gaia BH3: a 33 $M_\odot$ dormant BH discovered in Gaia preliminary astrometry

Dr Pasquale Panuzzo[1], Dr Tsevi Mazeh[2], Dr Frédéric Arenou[1], Dr Berry Holl[3]

[1]CNRS – Observatoire de Paris – Université PSL. [2]School of Physics and Astronomy, Tel Aviv University. [3]Department of Astronomy, University of Geneva

Abstract

The validation activities in preparation of the Gaia DR4 resulted in the discovery, in the preliminary astrometry, of a binary system, hosting a dormant black hole with an exceptional mass. Black holes of these masses have been detected only in BH mergers in distant galaxies via gravitational waves. The fact that the stellar companion is an old very metal-poor giant of the Galactic halo supports the scenario that the progenitors of the high-mass BHs detected by gravitational-wave telescopes are metal-poor massive stars. The Galactic orbit of the system and its metallicity indicate that it might belong to the ED-2 stream, likely a globular cluster accreted by the Milky Way, giving hints on the formation mechanism of this binary system. The discovery is an example of the impressive impact of the Gaia mission on all branches of stellar astrophysics. We will describe the discovery of Gaia BH3, its implications, and report on results obtained by the community on this astonishing object.

RECOMMENDATIONS FOR INTERNATIONAL STANDARDS FOR CISLUNAR PNT

SUSAN G STEWART

US NAVAL OBSERVATORY

Abstract

The escalation of planned activity in the cislunar environment by international space programs and scientific communities creates a pressing need for the development of fundamental standards to support cislunar navigation and research. The International Astronomical Union (IAU) and its international partner organizations in geodesy and time have well-established precedents in coordinating astronomical standards for international adoption. The IAU Commission A3 (CA3) on Fundamental Astronomical Standards is leading efforts to establish standards in lunar reference frames in coordination with partner organizations. As a first step, IAU CA3 proposes three recommendations for resolutions at this IAU General Assembly. Specifically, there is a call from the astronomical community for a relativistic reference system and coordinate time based on the lunar center-of-mass to support lunar-based activities, much like the convenience of a geocentric coordinate system (GCRS) for Earth- based observations. The proposed Lunar Celestial Reference System (LCRS) and its associated Lunar Coordinate Time (LTC) will be defined. The IAU CA3, the IAU Working Group on Time and Metrology and representatives from The International Bureau of Weights and Measures (BIPM) have collectively recognized the need for the adoption of a coordinated universal lunar time standard. Preliminary discussion on this and other issues for next steps for cislunar standards will be presented.

Validation of KSA-Geoid by vertical deflection Observations

OTHMAN ALRUBAYYI[1], Sultan Al-Shahrani[2], Iurii Golubinka[2], Eslam Abdulsamie[2], Abdullah Al-Qahtani[2], Tariq Alqarni[2], Rossen Grebenitcharsky[2]

[1]Head of SRS Department, GEOSA, Kingdom of Saudi Arabia,. [2]

Abstract

The KSA-GEOID21 is the latest geoid model for the territory of the KSA and service as 3D vertical datum of the National Vertical Reference System. The KSA-GEOID21 includes two versions: gravimetric and hybrid and allows computing orthometric heights all over the KSA with an accuracy of 1.5 - 2.5 cm The Executive Directorate of Geodesy (EDG) of GEOSA intends to initiate a project of independent validation of its most recent geoid models KSA-GEOID21 (gravimetric and hybrid versions) and its densification in specific regions of KSA by utilization of astronomical observations of deflections of the vertical (deflection of the plumb line) conducted, using DIGITAL-ZENITH CAMERA (DZC). The results of the DZC observation will be an important source of accurate, reliable, and independent data that can be utilized for geoid model validation and improvement of its accuracy. The main project objective is to perform observations of deflections of the vertical on 500 benchmarks of the National Vertical Network utilizing DZC. The basic unit of DZC observation activities is a rotation position at which the acquisition of a number of images and tiltmeter data are taken, typically it takes 1.5 - 2 minutes to collect the data, rotate to the next position and level the instrument. The minimal observation session constitutes 16-30 rotation observations. and the larger number of observations in the session improves the accuracy of vertical deflection.

The relation between session duration and expected accuracy of vertical deflection are as follows:

Accuracy level Duration Number of Session Expected Accuracy

Minimum accuracy up to 50 minutes 1 0.1-0.2 arcsec

Average accuracy ~2 hours 2-3 <0.1 arcsec

Maximum accuracy 2-3 hours 5-10 0.05 arcsec

Enhancing the studies of reference frame ties and millisecond pulsar formation channels with high-precision VLBI astrometry of millisecond pulsars

Dr Hao Ding

Mizusawa VLBI Observatory, National Astronomical Observatory of Japan

Abstract

Millisecond pulsars (MSPs) are the fastest-spinning neutron stars. Thanks to their superb time-keeping ability, MSPs have provided sharp tests of gravitational theories, and have been collectively used to constrain the stochastic gravitational-wave background (GWB). Precise astrometric studies of MSPs are desired in many ways. In this talk, I will mainly focus on two scientific prospects promised by MSP astrometry. Firstly, as I will explain in the talk, the velocity distribution of MSPs is likely multi-modal. VLBI astrometry of MSPs holds the key to constraining the MSP velocity distribution, which is directly linked to the formation channels of MSPs. Secondly, VLBI and timing observations of MSPs can jointly refine the connection between the kinematic and dynamic reference frames, which would better quantify the systematics in pulsar timing array studies. Alongside the scientific discussions, I will describe the main challenges the two studies are facing, and outline some innovations in data reduction and analysis that may help us overcome the challenges.

Analytical Methods for Celestial Mechanics: applications and some examples

Dr Irene De Blasi

University of Turin (Italy)

Abstract

Many problems coming from Celestial Mechanics can be studied using the tools coming from Nonlinear Analysis and Dynamical Systems Theory. Some of those models concern for example the motion of bodies subjected to the mu- tual gravitational attraction (the celebrated N-body problem) or the geocentric motion of a satellite, influenced both by the Earth's shape and the third-body gravitational attraction of external masses. The seminar aims to describe some of these models, focusing on the analytical techniques which can be used, case by case, to study their dynamical properties.

Time on the Moon in the context of various relativistic time scales in the Solar System

Sergei Klioner

Lohrmann Observatory, Technische Universität Dresden, 01062 Dresden, Germany

Abstract

Recent plans of various space agencies to boost their activities on the Moon and in its neighborhood makes it necessary to define the relativistic coordinates for the Moon and in particular, to carefully discuss all aspects on the relativistic time suitable for the Moon. The IAU 2000 framework for relativistic reference systems establishes the fundamental principles for physically adequate reference systems and should be used to define the local relativistic reference systems for each solar system body of interest. The corresponding relativistic coordinate time are always integral part of those reference systems. The proposed IAU Resolution use that framework to define the reference system for the Moon. After a brief introduction into the IAU 2000 framework, we will discuss the remaining freedom of those reference system: the orientation of the spatial axes and an arbitrary scaling of the time and spatial axes (e.g. TDB-compatible vs. TCB-compatible quantities). We put the discussion into context of the similar definition for other bodies of the Solar System: Mars and Mercury. And discuss pros and contras of various choice of the scaling.

speckle

The dependence of the statistical characteristic parameters of speckle pattern on both roughness variance and its phase correlation Mohamed farag

faculty of science helwan university

Abstract

The advent of the James Webb Space Telescope (JWST) marks a transformative era in planetary science and exoplanetary research. With its unparalleled capabilities in observing across the electromagnetic spectrum, JWST promises to unveil the secrets of planetary atmospheres, surfaces, and compositions both within our solar system and in distant exoplanetary systems. Furthermore, when coupled with speckle imaging techniques, JWST's imaging capabilities are enhanced, enabling the resolution of finer details and the mitigation of atmospheric distortions. This abstract explores the symbiotic relationship between JWST and speckle imaging, demonstrating how their combined power propels our understanding of planetary phenomena. From deciphering the atmospheric dynamics of exoplanets to mapping the surface features of celestial bodies, this integrated approach opens new horizons for planetary exploration, offering insights into the diversity and complexity of worlds beyond our own. we study the dependence of the statistical characteristic parameters of speckle pattern on both roughness variance and its phase correlation under the condition of dependent phases of the scattered waves.

Star cluster membership with DBSCAN

Dr Priya Shah

Maulana Azad National Urdu University, Hyderabad, India

Abstract

In this paper, we apply the machine learning clustering algorithm Density Based Spatial Clustering of Applications with Noise (DBSCAN) to study the membership of stars in nine open clusters (NGC~2264, NGC~2682, NGC~2244, NGC~3293, NGC~6913, NGC~7142, IC~1805, NGC~2352, NGC~2243) based on Gaia DR3 Data.

This sample of clusters spans a variety of parameters like age, metallicity, distance, extinction and a wide parameter space in proper motions and parallaxes. We obtain reliable cluster members using DBSCAN as faint as $G_{mag}\approx 20^m$ and also in the outer regions of clusters. With our revised membership list, we plot color-magnitude diagrams and we obtain cluster parameters for our sample using ASteCA and compare it with the catalog values. We also validate our membership sample by spectroscopic data from APOGEE and GALAH. This paper demonstrates the effectiveness of DBSCAN in membership determination of clusters.

Open star cluster membership limitations with Gaussian Mixture Modelling

Prof Syed Najamul Hasan, Dr Priya Shah

Maulana Azad National Urdu University, Hyderabad, India

Abstract

We have used Gaussian Mixture Modelling to determine membership in twelve star clusters with Gaia DR3 data. We have a varied sample of clusters in terms of distance, age and galactic position. We assess the results using a metric called the Modified Siluette Score and find that GMM does not work too well with clusters at distances larger than 3 kpc. We confirm our membership results using Spectroscpic data from APOGEE and GALAH and use ASteCA to determine parameters of our cluster sample.

Rubin's LSST as a large-scale time-domain photometric survey

Professor Zeljko Ivezic

AURA/University of Washington

Abstract

The Legacy Survey of Space and Time (LSST), the first project to be undertaken at the new Vera C. Rubin Observatory, will be the most comprehensive optical astronomical sky survey ever undertaken. Starting in 2025, Rubin Observatory will obtain panoramic images in ugrizy passbands covering the sky visible from its location in Chile every clear night for ten years, resulting in close to a thousand observations of each position across half of the celestial sphere. About 20 billion galaxies and a similar number of stars will be detected using this 60 petabyte image dataset. LSST data will be used for investigations ranging from cataloging potentially hazardous near-Earth asteroids, to stellar and black hole astrophysics, and fundamental physics such as the characterization of dark matter and dark energy. I will briefly overview scientific goals behind this project, provide a construction status update, and finish with a discussion of tools and plans relevant for time-domain science with LSST.

The Habitable Worlds Observatory: Mission Overview and the Path to Discovery

Prof. Kevin France

University of Colorado

Abstract

The discovery of thousands of planets orbiting stars beyond the solar system has fundamentally shifted our view of Earth's place in the Universe, has captivated the public imagination, and has transformed research priorities in astrophysics. Those accomplishments have put us in a position to ask the fundamental question "Are we alone?" and on a path to developing the technical tools to answer this question. The US 2020 Astrophysics Decadal Survey (Astro2020) has recommended the development of a space observatory to investigate the frequency of habitable exoplanets, search them for signs of global biospheres, and perform a wide range of transformative astrophysics.

NASA has dubbed that telescope the Habitable Worlds Observatory (HWO). In this talk, I will present the recommendation for the development of HWO based on Astro2020's key science goals in exoplanets and astrophysics. Maturing the science, technical, and programmatic path to HWO will require enthusiastic collaboration between a wide range of disciplines, interests, and stakeholders. I will discuss NASA's efforts for maturation of the HWO concept; highlighting how this process builds on the LUVOIR and Habex mission studies, key challenges, current activities, and opportunities for the global astronomical community to get involved in the mission development. Continuing out into future decades, HWO will serve as the first mission in a new generation of Great Observatories that will revolution our understanding of the Universe and our place in it.

Gearing the 32-metre radio telescope for data-intensive opportunities

Dr Emmanuel Proven-Adzri[1], Dr Theophilus Ansah-Narh[1], Dr Johannes Allotey[2], Dr Emmanuel Bempong-Manful[3]

[1]Ghana Space Science and Technology Institute. [2]University of Cambridge. [3]University of Manchester

Abstract

This abstract presents an overview of the data-intensive research capabilities and collaborative initiatives associated with Ghana's 32-metre radio telescope. The telescope conducts cutting-edge astrophysical investigations focusing on methanol masers in star-forming regions, radio continuum sources, pulsars, and active galactic nuclei (AGN). With full Very Long Baseline Interferometry (VLBI) operation expected by the close of this year, substantial data volumes, reaching multiple gigabytes daily will be generated by the telescope. Beyond traditional astronomical research, the high-performance computing resources at the telescope site have been instrumental in solving complex machine-learning problems. Notably, these applications include the detection of pulmonary diseases in chest X-rays and predicting corporate bankruptcy in financial institutions, showcasing opportunities and impact on data science. Collaborations with DARA Big-data and the University of Bristol have been established, fostering cross-disciplinary projects and knowledge exchange. This collaboration enhances the functional computing infrastructure for data storage, curation, calibration, and access. As a result, students and researchers, regardless of location, will have the opportunity to remotely access and contribute to the wealth of data generated. We seek further collaborations to leverage the data-intensive opportunities presented by Ghana’s 32-metre radio telescope. This extends beyond astrophysical research, opening doors for interdisciplinary studies and promoting the development of advanced computing infrastructures. We invite interested parties to explore new collaborative ventures that will not only benefit Ghana but also contribute to the advancement of science in the broader sub-region.

ULTRASAT: Revolutionizing our view of the transient universe

Dr. Yossi Shvartzvald

Weizmann Institute of Science

Abstract

ULTRASAT is an Isreali-led scientific satellite, that is planned to be launched to a geo-stationary orbit in 2027. It will carry a telescope with an unprecedentedly large field of view (200 squared degrees) and UV (230-290nm) sensitivity. These unique properties will enable us to detect and systematically study transient astronomical events within an extra-Galactic volume that is hundreds of time larger than that accessible to current observatories. ULTRASAT's measurements will have a broad science impact across the fields of gravitational wave sources, supernovae, variable and flare stars, active galactic nuclei, tidal disruption events, compact objects, and galaxies. In this talk I will review ULTRASAT's key science goals, its unique technical properties, and the project's structure and status.

Synergies between ngVLA and SKA

Dr Anthony Beasley[1], Prof. Philip Diamond[2]

[1]National Radio Astronomy Observatory. [2]Square Kilometer Array Observatory

Abstract

The coming decade will see the construction and early science operations of several new radio instruments, operating across a wide range of sensitivities, frequencies and angular scales. The multi-national SKA is under construction in South Africa and Australia, ngVLA is being planned for a construction start later this decade, and instruments like CHIME, DSA-2000, ngEHT and others will explore the radio universe like never before. In this talk, we will discuss the scientific, technical and operational synergies being planned for the SKA and the ngVLA, and provide an overview/status of the projects. Following a highly-successful international conference in 2023, we are continuing to explore and coordinate our efforts to enable new opportunities for the global research community.

Automatized 8inch reflective telescope

Mr Biruk Abrham Abte

Space Science and geospatial institute

Abstract

This project presents the design and construction of an automated 8-inch reflective telescope, tailored for the advancement of personal experience in amateur astronomy and educational purposes, particularly in regions with limited access to sophisticated astronomical equipment. Motivated by the lack of resources and knowledge prevalent in developing countries, this initiative seeks to empower individuals with the tools and understanding necessary to engage meaningfully with the wonders of the cosmos.

The telescope's design prioritizes accessibility and ease of use, utilizing readily available materials and components wherever possible. The automated functionality enhances user experience by simplifying the process of locating celestial objects, thereby reducing barriers to entry for amateur astronomers. Detailed instructions and guidelines accompany the telescope, catering to individuals with varying levels of technical expertise.

Through hands-on engagement with the construction process and subsequent use of the telescope, users gain valuable insights into optical principles, mechanical engineering, and celestial navigation. This experiential learning approach fosters a deeper appreciation for science and technology while nurturing curiosity and critical thinking skills.

Furthermore, the telescope serves as a valuable educational tool in formal and informal settings, facilitating astronomy outreach programs and classroom activities. By democratizing access to astronomical equipment and knowledge, this project aims to inspire and empower the next generation of scientists and enthusiasts, regardless of geographical or socioeconomic constraints.

Present and future development of neutrino telescopes

Prof Soebur Razzaque

University of Johannesburg

Abstract

A new era of neutrino astronomy has begun with detection of high-energy neutrinos by the IceCube telescope in Antarctica from astrophysical sources. A few other telescopes such as the KM3NeT in the Mediterranean and Baikal-GVD are under construction or in the expansion phase. Many more are in the proposal stage. Data from all these facilities will transform the field and lead to a precision era of neutrino astronomy. In this talk I will discuss the performance of the present neutrino telescopes and discuss future developments to make neutrino astronomy truly possible.

Updates from the Australian SKA Regional Centre (AusSRC)

Dr Karen Lee-Waddell

Australian SKA Regional Centre

Abstract

The Australian SKA Regional Centre (AusSRC) is part of an international computing and data delivery network that will enable ground-breaking science by providing the connection between the SKA telescopes and the science community. Currently, AusSRC is working with SKA precursors, primarily ASKAP and the MWA, to test and develop scalable data analysis strategies and automated workflows that can eventually be applied to data from the SKA telescopes. We are also part of the increasing effort to prototype various aspects of the international SRC Network (SRCNet), such as testing data distribution and archiving frameworks, establishing operational requirements and pipelines, and building user interfaces. I will provide an update on our progress and an overview of how the AusSRC is facilitating the scientific output of the SKA research community.

The Bulgarian Astronomical Observatory Rozhen - present equipment and future development

Prof. Evgeni Semkov

Institute of Astronomy and NAO, Bulgarian Academy of Sciences, Sofia, Bulgaria

Abstract

National Astronomical Observatory Rozhen is situated in the Rhodope Mountains at 1750 m altitude and it is a leading astronomical center in the South-East Europe. The observatory is equipped with four telescopes for photometric and spectral observations: 2 m RCC telescope, 1.5 m RC robotic telescope, 50/70 cm Schmidt telescope and 60-cm Cassegrain telescope. Since the Rhodope Mountains are one of the few places in Europe preserved from light pollution, we plan to develop optical observations in the future as well. The advantage of our observatory is its location in Europe in the UTC+02:00 time zone, where very few large telescopes are located. This allows us to participate in many international collaborations for observations of rapidly changing objects: variable stars, blazars, occultation by asteroids and by trans-Neptunian objects, near-Earth object, etc.

Thanks to the national funding of scientific infrastructure, we are successfully renewing the observation equipment at the Rozhen observatory. Our most recent acquisition is the 1.5 m robotic telescope, with which regular observations have begun since the summer of 2023. We are also planning to replace the old Cassegrain telescope with a new 80 cm RC remote control telescope. New CCD cameras and spectrographs needed for quality astronomical observations will also be delivered in the coming years. As part of the Rozhen observatory, in 2025, the construction of a station of the LOFAR low-frequency radio telescope will begin.

The Cherenkov Telescope Array Observatory

Prof. Markus Boettcher[1], The CTA Consortium[2]

[1]North-West University. [2]N/A

Abstract

The Cherenkov Telescope Array Observatory (CTAO) is the next generation ground-based gamma-ray telescope
facility, currently under construction. It is envisioned to ultimately consist of about 100 Cherenkov telescopes on two sites: a northern site on the Canary Island of La Palma, Spain, and a southern site near Mt. Paranal, Chile. The initial array (called "Alpha configuration") with over 60 telescopes is currently
expected to be completed by 2028. The CTAO is expected to be about 10 times more sensitive than currently
operating Cherenkov telescope facilities (H.E.S.S., MAGIC, VERITAS) and provide significantly improved spatial resolution and extended energy coverage, towards both lower and higher energies. A prototype of the large-sized telescopes (LSTs) is already fully operational on the northern site of La Palma (called LST-1). This review presents the current status of the CTAO construction and science prospects for the full CTAO.

Machine Learning Explorations in GRB Studies: From Classification to Extended Emission Identification

Mr. Keneth Garcia-Cifuentes[1], Dr. Fabio De Colle[1], Dr. Rosa Becerra[2]

[1]Instituto de Ciencias Nucleares, Universidad Nacional Autónoma de México. [2]Università degli Studi di Roma Tor Vergata

Abstract

Gamma-ray bursts (GRBs) have traditionally been categorized based on their durations. However, the emergence of extended emission (EE) GRBs, characterized by durations higher than two seconds and properties similar to short GRBs, challenges conventional classification methods. In this talk, we delve into GRB classification, focusing on a machine-learning technique (t-distributed stochastic neighbor embedding, t-SNE) for classification and the identification of extended emission in GRBs, and its hyper-parameter optimisation.

Furthermore, we introduce an innovative tool, ClassipyGRB, designed for astronomers whose research centers on GRBs. This versatile Python3 module enhances the exploration of GRBs by offering nteractive visualizations of their light curves and highlighting shared attributes. With ClassipyGRB, astronomers can swiftly compare events, identifying resemblances and exploring their high-frequency characteristics. This tool uses the power of proximity analysis, enabling rapid identification of similar GRBs within seconds.

The Technologies Needed for HWO Including the Role of Cubesats and Small Space Missions In Paving the Path to HWO

Dr Paul Scowen

NASA Goddard Space Flight Center

Abstract

The Habitable Worlds Observatory has been identified as the top recommendation by the US National Academy of Sciences (NAS) in their 2021 Decadal Report. The ambitious mission will deliver groundbreaking coronagraphy performance to directly measure reflection spectra from exoplanets in search of habitability while at the same time providing a suite of instruments to perform transformational astrophysics. Enabling ultraviolet throughput together with remarkable optical stability all present a series of challenges. NASA has established a program to develop both science and technology at the recommendation of the NAS - the Great Observatories Maturation Program (GOMAP) - which is studying both the science drivers and the technological capabilities the community can bring to bear within the next 5 years to establish a working architecture. The path to delivering the Observatory's needs will be rooted in leveraging existing technological investments by NASA and other agencies, but a range of development strategies is needed which includes both laboratory and space-based demonstration and advancement. In this talk we will discuss the state of the art of several key technologies and plans in place to advance them using a range of methodologies.

A Fiber-fed Mobile Telescope and Enclosure for the CHARA Array

Dr Christopher Farrington, Dr Gail Schaefer, Dr Douglas Gies, Dr Edgar Ligon, Dr Theo ten Brummelaar, Dr Nicolas Scott, Dr Nils Turner, Dr Rainer Kohler

Georgia State University - CHARA

Abstract

The CHARA Array is currently developing a 7th telescope to extend the existing 6 telescope array. This new telescope is the pathfinder for the Michelson Array concept and is a mobile 1-meter telescope that can be placed at multiple locations around the Mt. Wilson site. Each location will consist of a concrete pad and end points of optical fibers from the CHARA optical delay and combiner lab. This will enable new short baselines of 20-30m for imaging the surfaces of large stars and new long baselines on the order of ~600m for resolving small stars. This can be expanded to 1km maximum baseline. These baselines will be used in conjunction with the existing 15 baselines that range from 34 to 331m. The new telescope is a custom 1m Ritchey-Chretien made by Planewave Instruments. Moving such a telescope around the observatory presents some unique challenges. To house and move the telescope we have designed a mobile enclosure that will utilize a heavy-duty trailer, skid-steer, a lifting system, and a customized telescope dome. Once in place on the pad the telescope will be unlocked and raised and a kinematic pier adapter placed underneath the telescope. The telescope is then lowered onto the adapter, ensuring a stable connection to the ground and isolation from the enclosure. A connection box at each pad will have hook-ups to power, communications, and the optical fibers. Then the telescope can make use of the same optical delay lines and beam combiners as the other CHARA Array telescopes.

Revealing quasar surroundings using coronagraphs

Dr. Bin Ren

Côte d'Azur Observatory

Abstract

The host galaxies of bright quasars have been difficult to image due to the overwhelming light from the quasars. Using coronagraphs and well-chosen reference stars, we can block a quasar and remove its residual light to reveal the surrounding environments. With Hubble Space Telescope's STIS coronagraph, we recently tested this approach for the first time for 3C 273 the prototypical quasar. Being the only operating space-based coronagraph in visible light, our study validates the coronagraph usage on extragalactic sources into the central kilo parsec region of quasars. This bridges the gap between classical imaging and interferometric studies, allowing for new insights for quasar host studies.

A Purpose-built Stellar Intensity Interferometer Array SIITAR for high angular resolution imaging of stellar surfaces and the study of stellar dynamics

Dr Colin Carlile[1], Prof Dainis Dravins[1], Dr Brian Thorsbro[2]

[1]Astrophysics, Lund Observatory, Lund University, Sweden. [2]Observatoire de la Côte d'Azur, Laboratoire Lagrange, Nice, France

Abstract

Stellar Intensity Interferometry (SII) promises significant gains in angular resolution. Hanbury Brown et al. measured the diameters of 32 MS stars with their SII setup at Narrabri at resolutions of ~2mas. This iconoclastic work heralded the age of Quantum Optics. In order to realise the potential of SII further, arrays of 10s, 100s or even 1000s of telescopes (light collectors) located kilometers apart are required. The number of telescopes & their separations (baselines) determine the quality of the derived images.

Recently SII has undergone a renaissance. Data from existing Cherenkov arrays: VERITAS, H.E.S.S. & MAGIC are very encouraging. ASTRI, a 9-telescope array under construction, will access 36 static baselines, increasing to ~400 as the target traverses the sky. Studies that edge towards an imaging of the star itself are on the horizon. With the Cherenkov Telescope South's potential 96 telescopes, angular resolutions of ~40μas will become possible. Recording ~50,000 baselines in a single night will yield detailed images of bright stars.

Intriguingly, even higher resolution images (~5μas) of bright MS stars would result from a dedicated SII array. Here we present a concept for such an SII Telescope ARray, SIITAR, with up to 2048 light collectors on a ~20 km elliptical footprint. We are inspired by the ambitious Deep Synoptic Array 2000 to be built in the Nevada desert. Partnering with DSA-2000 on an already chosen site would reduce both construction time & cost, promising concurrent measurements in both the radio & optical bands.

Using GIS for Site Suitability Analysis for Siting a Radio Telescope in Kenya

Mr. Francis Ochieng[1,2], Dr. Ing. Sammy Musyoka[1]

[1]University of Nairobi. [2]NEPAD/APRM Kenya Secretariat

Abstract

Radio sources in outer space emit radio signals that travel to the Earth. Even though the radio signals are very weak, they can reach the earth's surface because they can penetrate dust in the atmosphere. However, because of constant man-made radio frequency interference, it is challenging to detect them from any location. This is the reason why sites hosting radio telescopes are carefully chosen. The objective of this study is to use GIS in finding suitable sites for siting a radio telescope in Kenya. Multiple-Attribute Decision Making (MADM) process of GIS-based Multi-Criteria Decision Analysis (MCDA) in AHP was employed in the search for suitable locations. The main datasets used in the study are: wind speed, national electricity grid network, rainfall, national mobile cell towers, DEM, and land use land cover (LULC). Suitable sites are: Turkana, Marsabit, Mandera, Wajir, Isiolo, Samburu, West Pokot, Trans Nzoia, Bungoma, Baringo, Laikipia, Meru, Nakuru, Tana River, Narok, Kajiado, Nyeri, and Nyandarua

Whereas there are proposals from radio astronomy enthusiasts in Kenya to have Longonot Earth Station refurbished to a radio astronomy site as was with Ghana Radio Astronomy Observatory (GRAO), it was observed that the defunct earth station currently suffers from higher RFI caused by increasing human settlement around the station. This study clearly shows that GIS can be applied in an MCDA to perform site suitability analysis in radio astronomy. It is recommended that further RFI, wind gradient, atmospheric dust, precipitable water vapor, and site suitability analysis be conducted in each suitable county.

Enabling X-ray astronomy from anywhere – XMM-Newton data analysis in the cloud

Dr Peter Kretschmar[1], Ms Esin Gübalhar[1], Mr Aitor Ibarra[2], Dr Ivan Valtchanov[2], Dr Richard Saxton[2], Dr Anthony Marston[1]

[1]European Space Agency, ESAC, Spain. [2]Telespazio UK for European Space Agency, ESAC, Spain

Abstract

ESA's XMM-Newton satellite has been operating as an open X-ray observatory since the year 2000, producing high quality scientific results over all these years and with an unflagging interest by the community.

The public XMM-Newton Science Archive (XSA) makes XMM-Newton data freely available to the world. Together with the data the XMM-Newton project provides the Science Analysis Software (SAS) which is also free to download and use but requires specific installation.

As an additional service to the community the XMM-Newton Science Operations Centre has been providing a Remote Interface for Science Analysis (RISA) via the XSA but with somewhat limited functionality compared to the full software suite.

In this poster we report on the efforts to make the full range of XMM-Newton science analysis accessible via cloud platforms, specifically via the ESA Datalabs initiative. Common analysis threads are being made available via user-friendly Python interfaces and the full set of tools are accessible for more experienced users, who can freely access the public data in the archive.

This initiative opens new possibilities for any interested researcher via the internet and web browsers, lowering the barriers for access to the exciting world of X-ray astronomy.

Imaging the sky with the Tianlai Cylinder Array: simulation and analysis

Dr. Kaifeng Yu, Dr Shifan Zuo, Dr. Fengquan Wu, Dr. Yougang Wang, Xuelei Chen

National Astronomical Observatories, Chinese Academy of Sciences

Abstract

The Tianlai cylinder array is a pathfinder for developing and testing 21cm intensity mapping techniques. It observes the sky by drift scan. We use numerical simulation to assess how its measurement is affected by thermal noise and the errors in calibration and map-making process, and the error in the sky map reconstructed from a drift scan survey, in the single frequency, unpolarized case. The beam is modelled by fitting to the electromagnetic simulation of the antenna, and the variations of the complex gains of the array elements are modelled by Gaussian processes. Mock visibility data is generated and run through our data processing pipeline. We find that the accuracy of the current calibration is limited primarily by the absolute calibration, where the error comes mainly from the approximation of a single dominating point source. We then studied the map-making algorithm with regularization. Discarding modes with singular values smaller than a threshold could generate visible artifacts in the map, though these are less visible in the Tikhonov regularization. The angular power spectrum of the reconstructed map show that the current Tianlai cylinder pathfinder, which has a shorter maximum baseline length in the North-South direction, would lose a significant fraction of higher angular modes when noise is present. The performance can be improved by reconfiguration of the array feed positions.

The VO, FAIR Principles and Open Science

De Bruce Berriman

Caltech/IPAC

Abstract

The Virtual Observatory (VO) is a global ecosystem of interoperating services that connect worldwide data archives. The VO is implemented in all major astronomy archives through common interfaces developed by the 22 members of the International Virtual Observatory Alliance (IVOA). It was founded in 2002, and the latest members, the SKA Observatory and the Kazakhstan Virtual Observatory, joined in 2022. The IVOA has since its inception supported the goals of Open Science and what are now known as FAIR principles: Findable, Accessible, Interoperable, Reusable. Implementation of the common interfaces, defined and documented as what are called VO protocols, go a long way towards implementing the FAIR principles. A total of eleven of the 16 enumerated FAIR principles are or will be implemented when VO protocols are employed. The remainder are generally out of scope for the IVOA. The VO acts a democratizing influence in astronomy: it provides equal access to worldwide public data sets to under-served communities as to large data centers, and enables international participation in scientific research and education. Thus astronomers from many different communities are positioned to participate in the big science questions emerging in astronomy in the 2020s.

Astronomical Polarimetry across the Spectrum

Dr. Juan Diego Soler

INAF

Abstract

Initially a fringe technique amongst the ones more traditionally used in observational astronomy, polarimetry has become a mainstream tool to explore the physics of the Universe in the past few decades. Large and small observatories now offer polarimeters, with technological developments in instrumentation and computing (including modelling) as major drivers of this flourishing. The whole electromagnetic spectrum is now actively being explored through polarimetry. I will briefly review the recent and forthcoming advancements in astronomical polarimetry, from gamma and X-rays to far-infrared and radio, and the paths of astronomical discovery they are opening.

The Characterization and Discovery of Solar System Small Bodies in Modern Astronomical Surveys

Dr. Joachim Moeyens

University of Washington

Abstract

Starting in 2025, the Vera C. Rubin Observatory will conduct a comprehensive survey named the Legacy Survey of Space and Time (LSST). LSST is predicted to discover six million minor planets. Claims in the literature have suggested that optically-derived asteroid diameters are only accurate to within 50% compared to IR-based estimates. We show that optical measurements can be used to constrain diameters with 0.4% bias and scatter of only 17%. LSST will discover minor planets by observing "tracklets": intranight linkages of two or more observations. The requirement to observe tracklets places a strong constraint on cadence and makes datasets not constructed with such a cadence unsuitable for discovery searches. We developed "Tracklet-less Heliocentric Orbit Recovery" (THOR), a cadence-independent discovery algorithm that does not require tracklets. We applied THOR to two weeks of observations from the Zwicky Transient Facility (ZTF) and show that it can recover 1.5-2x as many asteroids as its tracklet-based counterparts. We deployed THOR on the Asteroid Discovery, Analysis, and Mapping (ADAM) platform – a cloud-based discovery service which we name ADAM::THOR. We used ADAM::THOR to search just 0.2% of the exposures contained in the NOIRLab Source Catalog (NSC) and discovered 104 new minor planets. More recently, we have continued processing the remaining 99.8% of the NSC with a production-version of ADAM::THOR and will report on its status and latest results, including discovery yields, processing time, and the implications for tracklet-less discovery in the era of LSST.

TCSpy: Multiple Telescope Control System for 7 Dimensional Telescope (7DT)

Mr Hyeonho Choi[1,2,3], Dr Myungshin Im[1,2,3], Dr Ji Hoon Kim[1,2,3]

[1]Seoul National University. [2]SNU Astronomy Research Center (SNUARC). [3]Center for the Gravitational Wave Universe

Abstract

In this poster, we introduce TCSpy, an innovative software which is designed to efficiently control an array of multiple telescopes through the network-based communication. The primary objectives of TCSpy contain centralized control of multiple telescope, realization of diverse observation modes with multiple telescopes and a swift response to the follow-up transient observations. To achieve these objectives, TCSpy utilizes the ASCOM Alpyca, establishing robust communication among multiple telescopes. Through the integration of Alpyca, TCSpy achieves three distinctive observation modes with the rapid follow-up capabilities. 1. Spectroscopic mode: synchronizes all telescopes precisely to target the same coordinate with different filters, 2. Deep mode: controls all telescopes to observe the same coordinate, but with identical filter. 3. Search mode: all telescopes operate separately to scan wide regions for capturing time-sensitive astronomical transients swiftly. For the practical application of TCSpy, we implement TCSpy within the 7 Dimensional Telescope (7DT). 7DT is a telescope array consisting of 20 0.5-m telescopes, each equipped with a different filter set. The main scientific goals of 7DT encompass detecting the optical counterparts of gravitational wave sources and identifying kilonovae through fast follow-up spectroscopic observation. In addition to these goals, 7DT embarks on the 7 Dimensional Survey (7DS), acquiring time-series spectroscopy across the entire southern hemisphere sky. Here, we show how these scientific goals are accomplished with TCSpy and preliminary performance of TCSpy.

Analysis of Kepler “KIC 8462852” Light Curves using ML Techniques

Ms Fatemeh Fazel Hesar[1,2], Prof. Bernard Foing[1,2,3], Dr. Atefeh Javadi[4], Dr. Leila Sadeghi[5,4]

[1]EuroSpace Hub Academy. [2]Leiden University. [3]EuroMoonMars. [4]Institute for Research in Fundamental Sciences (IPM). [5]SPCRI

Abstract

The intricate patterns and hidden secrets embedded within celestial light curves hold immense potential for understanding the underlying physical processes governing the cosmos and identifying potentially habitable worlds in the context of exoplanet research. However, deciphering these patterns is often hindered by the complexity and noise inherent in light curve data. To address this challenge, we propose a novel multi-model regression approach that combines the strengths of Gaussian Process Regression (GPR), Linear Regression, and Random Forest Regression (RFR) to analyze light curve data effectively. This comprehensive approach enables us to uncover deep insights even in noisy and complex signals, particularly relevant for identifying exoplanets.

We leverage the wealth of Kepler light curve data and employ meticulous data collection and preprocessing techniques to utilize this multi-model regression approach. Our analysis of the KIC 8462852 dataset, a potential exoplanet host, demonstrates the effectiveness of our method in unveiling the complex interplay of periodic and non-periodic phenomena, providing valuable insights for exoplanet detection. This groundbreaking approach empowers us to decode the mysteries of light curves, paving the way for transformative insights into exoplanets and the search for habitable worlds.

30 years of improving VLBI - technology developments at JIVE

Mrs Marjolein Verkouter

Joint Institute for VLBI ERIC

Abstract

The Very Long Baseline Interferometry (VLBI) radio astronomical observing technique is booming. Due to massive technological improvements and cost reduction in digital equipment this techique is increasingly popular and able to address unique science questions such as imaging the shadows of black holes or localising Fast Radio Bursts within their host galaxies.

The Joint Institute for VLBI European Research Infrastructure Consortium (JIVE) celebrates is 30th birthday this year. JIVE, and its Technical Operations and R&D department's, core mission states "improve the VLBI technique in the widest sense". Over the institute's life time so far, many tools, products, and algorithms were developed that not only benefit the European VLBI Network, but have found application in other VLBI arrays, communities, or into the Common Astronomical Software Applications (CASA) standard radio data reduction package.

In this talk I would like to introduce some of those technological developments potentially relevant to current, and future instruments such as the SKA, from a software VLBI correlator providing unique science opportunities to global high-speed data recording and transmission tools (the EVN is the only VLBI array offering real-time correlation as standard observing mode), Jupyter-notebook based radio data processing with CASA, and supporting radio data (including raw visibilities) in the International Virtual Observatory, demonstrated by the inclusion of the EVN Archive in the VO. To address future scalability in data rates and volumes, currently developments include porting the correlator's algorithm to a TensorCore-based GPU platform and the fringe fit algorithm to the Python Dask framework.

Machine Learning Approaches to Study Star Formation and Black Hole Accretion in the MeerKAT/MIGHTEE Survey

Mr Walter Silima

The Inter-University Institute for data intensive astronomy (IDIA), University of Cape Town

Abstract

Galaxy formation and evolution are driven by two main physical processes: star formation and black hole accretion. Both processes can be traced via the synchrotron emission at radio wavelengths. However, a reliable classification of radio sources as star-formation-dominated sources (or Star-Forming Galaxies, SFGs) and black-hole-accretion-dominated sources (or Active Galactic Nuclei, AGN) is non-trivial and often requires extensive use of multi-wavelength data. Although significant effort has been put into classifying radio sources as SFGs or AGN over the decades, the rapid growth of radio data available from facilities such as the South African MeerKAT telescope, the Australian Square Kilometre Array Pathfinder (ASKAP), and eventually the Square Kilometre Array (SKA) requires the development of efficient and reliable automated classification techniques. In this study, we develop, optimise and compare supervised machine learning (ML) models such as Logistic Regression (LR), Support Vector Machine (SVM), K-Nearest Neighbour (*k*NN), Random Forest (RF) and Extreme Gradient Boosting (XGB) to classify radio sources detected in the MeerKAT International GHz Tiered Extragalactic Exploration (MIGHTEE)–COSMOS survey as SFGs and AGN. We found that supervised ML models perform very well in classifying SFGs and AGN detected in radio continuum surveys. All models performed well with accuracies greater than 90%, even when only 20% of the data was used to train models.

codeSMT – An Integrated Modelling tool for Segmented Mirror Telescopes.

Dr Prasanna Deshmukh

Indian Institute of Astrophysics

Abstract

Segmented mirror technology is slowly becoming a natural choice for upcoming telescopes of mid to large sizes. The challenge with the segmented primary mirror telescope (SMT) is to maintain the alignment of mirror segments against gravity, thermal and wind induced disturbances. This is achieved through an active control system using three actuators and six intersegment edge sensors. The conversion of sensor positions to required displacement in the actuator is carried out using a primary mirror control system (M1CS), which utilizes an interaction control matrix. As telescope size increases, control of segmented mirror telescope becomes more and more challenging due to its complexity and the presence of a high order system. So, the use of an Integrated model of the telescope becomes a necessity in the early design phase of the telescope for parameter selection and optimisation. A generic Integrated Modelling tool (codeSMT) for the design and analysis of a Segmented Mirror Telescope is developed at IIA. The codeSMT tool is built based on the state-space model of a soft actuator with Multiple-Input Multiple-Output (MIMO) capability to incorporate dynamic wind disturbance and vibration effects. A detailed error multiplier analysis can be performed numerically using this tool. A parameter sensitivity analysis can be performed to fine-tune the primary mirror control system variables. In this paper, I will present features and applications of the codeSMT tool along with a case study of the National Large Optical Telescope (NLOT) under design and development at the Indian Institute of Astrophysics.

MAGIC: a focal reducer for the study of active galactic nuclei

Roman Uklein[1], Eugene Malygin[1], Elena Shablovinskaya[1,2], Vladimir Amirkhanyan[1], Alexander Perepelitsyn[1], Irina Afanasieva[1]

[1]Special Astrophysical Observatory of Russian Academy of Sciences, Nizhny Arkhyz, Russia.
[2]Instituto de Estudios Astrofisicos, Facultad de Ingenieria y Ciencias, Universidad Diego Portales, Santiago, Chili

Abstract

We present the universal focal reducer MAGIC (Monitoring of Active Galaxies by Investigation of their Cores), which will be commissioned on the Russian 1-meter telescope in 2020. Three observing modes are currently implemented: photometry, polarization, and long-slit spectroscopy. MAGIC provides a wide field of view for photometry and a slit height for spectroscopy of ~12', and a field of view of ~6'.4 for polarization with a quadrupole Wollaston prism. This feature provides an efficient way to study extended nebulae and galaxies. The spectral mode in the range 4200-7000 AA provides a spectral resolution of R ~1000; for stellar objects up to 14 mag in mid-band filters with 1'' image quality over a 20 minute exposure, the photometric accuracy is better than 0.01 mag and the polarization accuracy is better than 0.6%. We will also highlight the current status and prospects of the project.

Scalable visualisation of large distributed data sets enabled by Virtual Observatory standards and tools.

Mark Allen

Centre de Données astronomique de Strasbourg. Strasbourg astronomical observatory, UMR 7550

Abstract

Surveys of the sky with current and future astronomical instruments will lead to very large volumes of data that are distributed in archives around the world. In the context of the international Virtual Observatory, hierarchical approaches have been developed to enable data-access and visualisation of very large data sets. This is based on the computation of multi-resolution representations of sky survey data, using the HEALPix indexation, and international agreement on the Hiearchical Progressive Survey (HiPS) standard of the IVOA. A network of ~20 'HiPS nodes' has been established, which provides access to ~1200 HiPS data sets, and a number of tools and services have been developed for visualisation of these data. I will present the capabilities of this open network using the example of the CDS Aladin service and the integration of Aladin Lite into various science portals. I will also highlight how the multi-resolution approach enables collections of pointed observations to be treated in the same systems as very large wide area surveys, and the new innovative scientific capabilities that are being built to exploit these rich data sets including cut-out services, and use the of time and frequency dimensions of the data.

EARTH'S PROTOTYPE, MOON'S FUTURE: MACHINE LEARNING FOR SMART AND SUSTAINABLE LUNAR CITIES

Mr Marc Crampe[1,2,3], Ms Fatemeh Fazel[3,2,4], Mr Jack Laffey[5,3,2], Ms Caitlin Robertson[5,3,2], Ms Molly Balfe[5,3,2], Dr Bernard FOING[3,2]

[1]IPSA Paris. [2]EuroMoonMars. [3]EuroSpaceHubAcademy. [4]Leiden University. [5]TE Dublin

Abstract

With the moon emerging as the next significant milestone in space colonization, it's crucial to learn from Earth's development and prioritize sustainability for lunar habitation. Using Earth as a blueprint, with its centuries of civilization and vast dataset is the best way to get ready for the next step.

What we have managed from now is using machine learning (ML) and Earth observation (EO) technologies to analyze urban organization and assist cities in expanding sustainably and strategically. We are now seeking to integrate insights from Fatemeh Fazel's work on ML with exoplanets and Molly Balfe and Caitlin Robertson's research on lunar mapping to develop a model for optimal organization of future moon villages and cities.

Recognizing that moon colonization will be an ongoing process requiring adaptability, our primary objective is to create an ML model, employing techniques such as Random Forest (RF) and Convolutional Neural Networks (CNN), to enable Moon urban mapping. This model will segment lunar areas based on key characteristics such as altitude, soil composition, and mineral deposits, while also considering the strategic placement of infrastructure elements as features which are crucial for city organization.

In conclusion, this comprehensive strategy offers Moon investors guidance in selecting the most suitable locations for infrastructure investment, fostering collaborative efforts towards lunar exploration and settlement in a sustainable way.

Supercharging transient science in the Rubin Observatory era

Prof. Renee Hlozek[1,2], Dr. Rob Knop[3], Prof. Gautham Narayan[4], The ELAsTiCC Team[5]

[1]Dunlap Institute of Astronomy and Astrophysics, University of Toronto. [2]Department of Astronomy and Astrophysics, University of Toronto. [3]Lawrence Berkeley National Laboratory. [4]University of Illinois at Urbana-Champaign. [5]LSST Dark Energy Science Collaboration

Abstract

Science with transients — objects that change in brightness over a given time frame in the optical sky — will be revolutionized by the Vera C. Rubin Observatory, which will see first light in 2025. The Rubin observatory will scan the entire sky visible from Chile every few nights in optical wavebands. Millions of 'alerts' that new objects have formed in the sky will be generated by the telescope each night, and several dedicated brokers will absorb those alerts, classify them into different categories and send them out into the community. These data will be stored and processed by data centres in the US and through International Data Access Centres (IDACS) provided by international partners.

I will describe the Extended LSST Astronomical Time-series Classification Challenge (ELAsTiCC), which challenged LSST broker teams to classify simulated Rubin alert streams in advance of the arrival of data. I will highlight how ELAsTiCC supported improvement of algorithms and methods in participant broker classification schemes, and how classification performance was evaluated in the challenge.

I will also describe the Canadian Data Intensive Astrophysics PLatform (CanDIAPL), a Canadian data centre under construction that will process and serve multi-wavelength data from Rubin and surveys at other wavelengths.

On-The-Fly interferometric imaging with the MeerKLASS survey

Dr. Suman Chatterjee

University of the Western Cape

Abstract

MeerKLASS, the MeerKAT Large Area Synoptic Survey, aims to survey large areas of the sky with MeerKAT in order to probe cosmology using the single dish HI intensity mapping technique, while producing continuum images with the interferometer. The target is to cover 10,000 deg2 on the UHF band with 25 uJy rms and 13'' resolution (a new survey in the L-band with the MeerKAT extension aiming at 5,000 deg2, 9 uJy rms and 5'' has also been proposed). The single dish survey requires a fast scanning mode at constant elevation in order to deal with systematics. This requires the use of the "On-The-Fly" (OTF) interferometric imaging technique to enable commensal observing for intensity mapping and interferometric imaging. In this work, we demonstrate that science-quality OTF interferometric continuum imaging with fast scanning speeds is possible with MeerKAT, using available MeerKLASS data. We develop a framework to transform MeerKLASS scan observations into OTF-format measurement sets and mitigate these issues. We use these measurement sets to produce OTF interferometric imaging snapshots and employ two different techniques to add multiple OTF snapshots. Till now we have processed OTF snapshots in L-band, that cover about 300 square degrees in the Southern sky and achieved an image sensitivity of ~140 uJy and we aim to reach about 30 uJy with the existing observations. In future, with many fold data acquisition by the MeerKLASS survey we expect to embark on the search for slow transient and deep imaging.

Enabling Future Breakthroughs in Time-Domain and Multi-Messenger Astronomy

Brad Cenko

NASA/GSFC

Abstract

Time-domain and multi-messenger astronomy (TDAMM) was highlighted as a frontier science pursuit in the coming decade by the 2020 Decadal Survey in Astronomy and Astrophysics in the United States. Given the rapid response and cross-facility coordination necessary to enable such science, well-defined standards play a critical role in this field reaching its full potential. I provide an overview of some of the most exciting scientific opportunities in the coming years in this science, and highlight the important role played by coordination in enabling those results.

3D Astronomical Visualization with Open Shading Language and Blender

Dr. Brian Kent

National Radio Astronomy Observatory

Abstract

Astronomical datasets now exhibit complexity that requires innovative displays of observational and theoretical data. We describe methods for using Open Shading Language (OSL) and Python to render 3D data in the software package Blender. The API allows control over camera angles, rendering, and GUI programming with the node compositor. Using OSL code and its C-like syntax with Blender allows for rendering and animating data. We show examples of all sky maps, 3D data cubes, and astronomical catalogs that can be examined in real time with a viewer, or with rendered output in high resolution.

Precipitable water vapour measurements at the potential sitesfor the Africa Millimetre Telescope

Mr Lott Frans[1], Prof Michael Backes[1,2], Prof Heino Falcke[3], Dr Tiziana Venturi[4]

[1]Department of Physics, Chemistry & Material Science, University of Namibia. [2]Centre for Space Research, North-West University. [3]Department of Astrophysics, Institute for Mathematics, Astrophysics and Particle Physics (IMAPP), Radboud University. [4]Istituto di Radioastronomia, Instituto Nazionale di Astrofisica

Abstract

The Event Horizon Telescope (EHT) is a network of antennas across the globe that is used to image super-massive blackholes (SMBHs). These antennas observe together in very long baseline interferometry (VLBI) at a frequency of 230 GHz to produce a single image. Since the release of the first image of M87* in 2019 and, subsequently, the image of Sgr A* in 2022 by the EHT collaboration, the focus has shifted to dynamically imaging blackholes. This has led to a search for possible sites to extend and fill the gaps within the EHT network. The Khomas highlands of Namibia have been found to have optimal conditions for astronomy and thus have been identified as one such area to add an observatory. The Gamsberg Mountain and the H.E.S.S. site are both located within the Khomas highlands and have been identified as potential sites for the AMT observatory. Precipitable water vapour (PWV) in the atmosphere is the main source of opacity when observing at millimetre wavelengths and therefore this study aims to establish the PWV content at the potential sites. Preliminary results show the overall PWV conditions at the Gamsberg Mountain was lower than that at the H.E.S.S. site. The winter period at both sites offered relatively low PWV's whilst the EHT window had relatively higher PWV at both sites in 2023. Both sites have higher atmospheric transmission during the winter period at 86 GHz and 230 GHz, with the possibility of conducting observations at 345 GHz at the Gamsberg Mountain under the best possible conditions of the winter period.

The next-generation Event Horizon Telescope

Dr. Sheperd Doeleman, Dr. Lindy Blackburn, Mr. Garret Fitzpatrick, Dr. Michael Johnson, Mr. Aaron Oppenheimer, Dr. Dominic Pesce, Dr. Jonathan Weintroub

Center for Astrophysics | Harvard & Smithsonian

Abstract

The next-generation Event Horizon Telescope (ngEHT) is project that will transform the EHT, creating an array that will be capable of making real-time and time-lapse movies of supermassive black holes on event horizon scales. These movies will resolve complex structure and dynamics in the immediate vicinity of the event horizon, bringing into focus not just the persistent strong-field gravity features predicted by General Relativity (GR), but details of active accretion and relativistic jet-launching that drive large scale structure in the Universe. This effort builds upon recent results by the Event Horizon Telescope (EHT): the first image of M87's supermassive black hole and its magnetic field structure, as well as resolved images of Sgr A*, the central black hole at the heart of the Milky Way.

These images, though scientifically rich, show that evolution of the EHT to a more capable array can address even deeper questions across physics and astronomy. The central concept behind the ngEHT is that the addition of many modest-diameter dishes at new geographic locations will enable high-dynamic-range imaging and time-resolved dynamical studies of the black hole boundary.

The central elements of the ngEHT include:

- Adding multiple 10-meter-class radio dishes in new geographic locations.
- Enabling tri-band (86, 230, 345 GHz) simultaneous observations to increase Fourier spatial frequency sampling and enable multi-frequency modeling and imaging.
- Increasing bandwidth for higher instantaneous sensitivity, moving to a per-station data capture rate of >256 Gbps.
- Developing a high-throughput data processing and analysis pipeline that speeds time to science.

Data Processing And Scientific Exploration of the Moon-Based Ultraviolet Telescope on the Chang'E-3 Lander

Dr. Gaurav Singh

National Astronomical Observatory of China

Abstract

We present the first results pipeline processed data observed from the Moon-based Ultraviolet Telescope (MUVT). The MUVT system is set up to perform multi-day observation activities that can monitor variables tars and active galaxies in the near ultraviolet band, which include variable stars, binaries, novae, quasars and blazers. MUVT is capable of detecting objects with a brightness down to magnitude 13. We will discuss the steps involved in processing the data and further analysis for the desired scientific usage. This includes the first results of the pipeline processed Level 2A and 2B data observed through MUVT over a decade.

A New Implementation of Convolutional Neural Networks for Astronomical Data

Faezeh Bidjarchian[1], Dr Mohamamd Akhlaghi[2]

[1]A freelance researcher. [2]CEFCA

Abstract

With the arrival of JWST, Euclid, LSST, J-PAS, and other whole sky surveys astronomers now have unprecedented access to massive amounts of data. However, processing and extracting knowledge from this data is a challenging task due to the enormous amounts of data. To enhance efficiency and functionality, software methods such as machine learning have gained significant attention in the physics research community in recent years. A deeper understanding of how these networks distinguish available objects and patterns to accurately predict new data is essential for their optimal usage.

In this talk, we have explored the limitations of current neural network architectures applied to astronomical data. Our research has revealed that the existing networks may not be well-suited for handling astronomical data and multiple issues can impact the performance of these networks. For example, our deep FITS images are 32-bit floating point and in many filters, so the conversion to 8-bit RGB JPEG format images causes the loss of valuable data early in the process. This is compounded by adding all filters together in inner layers, which may not fully capture the complexities of the data, and the presence of NaN values which are prevalent in astronomical data.

To address such and other limitations of current neural networks when applied to astronomical data, we are developing a dedicated program within GNU Astronomy Utilities (Gnuastro). Our implementation is designed to account for the such issues mentioned above problems.

LSST Discovery Alliance - Helping Scientists Use Rubin's Legacy Survey of Space and Time

Dr. Beth Willman

LSST Discovery Alliance

Abstract

LSST Discovery Alliance (LSST-DA) aims to maximize the impact of Rubin Observatory's Legacy Survey of Space and Time. On track to begin in 2025, this ground-based, optical survey will curate astronomical data at a scale never seen before, producing the ultimate map of our dynamic Universe. LSST-DA removes obstacles between Rubin LSST's data-intensive output and discovery by developing an ecosystem of bold programs that foster innovation, inclusion, and interdisciplinary collaboration. Through our programs, we can propel a revolution in humankind's understanding of the Universe while transforming the way we do science. This talk will highlight our approaches to lowering the barrier of engagement with data-intensive astrophysics experiments.

Unveiling the Instrument Polarization: Insights from the INdian Spectroscopic and Imaging Space Telescope (INSIST)

Dr Vineeth Valsan[1], Dr Sriram S[1,2], Ms Lorraine Maria Thomas[1], Ms Raveena Khan[2], Ms Namita M Kinnal[1], Professor Maheswar Gopinathan[2], Professor Annapurni Subramaniam[2]

[1]Christ University. [2]Indian Institute of Astrophysics

Abstract

The INdian Spectroscopic and Imaging Space Telescope (INSIST), a proposed Ultraviolet (UV) mission, aims to explore the UV-Visible region, generating high-quality images akin to the Hubble Space Telescope. Operating within the range of 150 nm - 500 nm, INSIST boasts a large focal area and delivers medium-resolution images (R ~ 1000- 2000). Utilizing an off-axis TMA design with a one-meter primary mirror, the telescope introduces instrumental polarization (IP) due to its optical configuration, which needs to be studied in detail.

Some degree of polarization is expected from every astronomical object, ranging from solar system objects to AGNs. Thus, polarimetry and polarization studies provide unique and powerful ways to discern the geometry and physical conditions of a large class of astronomical objects. Polarimetry, especially in UV, is an unexplored area, and having a polarimetric capability will add value to the mission. However, including a polarimetric capability in the mission requires elaborate and precise calibration. Understanding instrumental polarization is a vital component to achieving that.

This study comprehensively characterizes the instrumental polarization of INSIST using the Polarization Ray Tracing method and Pupil maps. Our analysis estimates the extent of IP, cross talk, and depolarization, enabling the correction of potential polarisation measurement errors. The critical insights into INSIST's instrumental polarization are obtained through simulations, ensuring accurate and reliable polarization measurements of celestial sources.

The Frequency Distribution System for the Mid-Frequency Square Kilometre Array radio telescope

Dr Michael Kriele[1,2,3], Mr Charles Gravestock[1,2], Dr Edward Gluszak[1,2], Mrs Neethu Thomas[1,2], Dr Eric Tyler[1,2], A/Prof Sascha Schediwy[1,2]

[1]University of Western Australia. [2]International Centre for Radio Astronomy Research (ICRAR). [3]Curtin University

Abstract

Phase-stabilized frequency distribution techniques, facilitated by optical fibre networks, serve as a basis for highly stable and precise frequency reference sources. These applications find significance in critical fields like atomic clock comparison, relativistic geodesy, and the phase-synchronization of radio telescope-based interferometric arrays. Notably, the largest frequency transfer networks cover distances of 2,200km and 4,800km, exhibiting residual instabilities between 10^{-16} and 10^{-19} with up to 94% uptime. The expansion of network reach involves combining fibre infrastructure and diverse technologies, necessitating the use of specialized equipment. An efficient design approach is required to expand these networks effectively, augmenting nodes and extending their total distance.

We present the Reference Frequency Distribution System for the Mid-frequency Square Kilometre Array telescope, with an emphasis on the Receiver Module (RM) performance. Generally, the system uses round-trip phase-stabilisation techniques to deliver a 3.96GHz clock signal to each of the 197 receptors. A novel configuration of Acousto-optical Modulators are used to achieve the actuation range required to suppress the phase fluctuations contributed by the overhead cables.

The RM functions as a precision low-phase noise, narrow-band microwave signal generator, synchronizing with phase-corrected optically transmitted frequencies. It ensures synchronous operation across all required frequencies, we demonstrate excellent stability and spectral purity through implementation of an innovative jitter-attenuating phase-lock loop design. The RM has >99.9% uptime, a maximum of 1% coherence loss >1000s, microwave-frequency signals with instability $<10^{-16}$, and a phase jitter performance of <100fs. Overall, the design presents a potential baseline for adaptation with other next-generation telescopes.

Mercurial MeerKAT & Fast ATA: towards a near-real time radio interferometric transient and variable detection pipeline

Distinguished Prof Oleg Smirnov[1,2,3], Dr Ian Heywood[4,1,5,2]

[1]Centre for Radio Astronomy Techniques & Technologies (RATT), Rhodes University. [2]South African Radio Astronomy Observatory (SARAO). [3]Institute for Radioastronomy, National Institute of Astrophysics (INAF IRA). [4]Oxford Astrophysics. [5]Breakthrough Listen

Abstract

The time domain is one of the last frontiers of radio astronomical imaging. Transient (and time-variable) astrophysical phenomena represent some of the most extreme physical processes in the Universe, and are also of extreme relevance to the ongoing search for SETI. Mercurial MeerKAT & Fast ATA (MM/FATA) is a joint initiative between Breakthrough Listen, Rhodes University, University of Oxford, and South African Radio Astronomy Observatory to develop a fast imaging backend for the MeerKAT and ATA telescopes. South Africa's MeerKAT is the most sensitive radio telescope in operation today, and initial (largely handcrafted) transient detection results point at a goldmine of hitherto unknown objects and new classes of objects waiting to be discovered. The recently upgraded Allen Telescope Array (ATA), on the other hand, has a very broad and agile frequency capability (1-12 GHz), and provides the capability to rapidly survey specific regions of interest. MM/FATA is a fast imaging pipeline that will be able to process imaging data in near real-time, perform transient detection, and extract lightcurves and dynamic spectra for objects of interest. Such a pipeline is made possible by a new generation of software tools developed at Rhodes, which are presented at this year's FM7 meeting. The eventual goal of the project is to deploy both (a) a fully commensal transient search backend operating on both telescopes in real time, and (b) an "archive mining" machine that can go back and mine the archives of existing data for these events.

Spanish Virtual Observatory: 20 years of public and community engagement

Dr J. Ricardo Rizzo[1,2], Dr Enrique Solano[1], Dr Francisco Jiménez Esteban[1], Dr Patricia Cruz[1], MSc Pedro Mas[1]

[1]Centro de Astrobiologia (CAB) INTA/CSIC. [2]ISDEFE

Abstract

It is described how the Spanish Virtual Observatory (SVO) contributed to the knowledge and best use of the VO tools and archives in its 20 years of existence. Since the beginning, SVO was heavily involved in a number of innovative activities aimed to promote the use of VO tools and archives, involving graduate and post-graduate students, and also amateur astronomers.

Specifically, we focus on two different actions: (1) the organization of events within large conferences; and (2) the development of specific schools.

Among the events, we highlight the successful organization of a Special Session within the EAS 2023 meeting. It was dedicated to current VO tools and the progressive incorporation of new approaches such as Machine Learning, Data Mining, and Big Data. We also describe the organization of a symposium in the frame of the Spanish Astronomical Society 2024 Annual Meeting, mostly focused on successful science cases based primarily in VO results.

Another set of actions is the continuous organization of specific VO Schools at different levels. The schools are developed both in-person and remote, sometimes co-hosted by universities and amateur astronomical societies. They are based on a learning-by-doing approach and makes use of the most common VO tools (such as TOPCAT and Aladin) and languages (such as ADQL and python/pyVO).

High-energy neutrino astrophysics and blazars

Dr. Paolo giommi

Center of Astronomy and Space Science (CASS), New York University Abu Dhabi. INAF-Osservatorio Astronomico di Brera. Institute for Advanced Study, Technical University, Munich

Abstract

In my presentation I will review some of the recent results on the identification of astronomical high-energy neutrinos with extragalactic cosmic sources.
I will particularly consider the class of blazars, which along with the more isolated case of the Seyfert galaxy NGC1068, constitute the most promising type of candidates counterparts.
I will report on the latest statistical correlation between the list of IceCube tracks reported so far as well as possible theoretical interpretation based on multi-wavelength data using novel methods.

European participation in the Habitable Worlds Observatory

Prof. Ana Inés Gómez de Castro

Universidad Complutense de Madrid

Abstract

Habitable Worlds Observatory (HWO) is a large infrared/optical/ultraviolet space telescope designed specifically to search for signs of life on planets orbiting other stars. The concept emerged from the recommendations of the National Academies of Science, Engineering and Medicine of the United States after the Decadal Survey on Astronomy and Astrophysics 2020. NASA funded four concept studies to aid the National Academies' decision that were participated by European Astronomers, most of them as representatives of their National Agencies. This participation included not only the participation in the science cases and science definition but also the design of specific instruments for the purpose. In this talk, I will address the progression of these activities.

Investigating the pupil dependence of the polarimetric sensitivity on SALT

Dr Danièl Groenewald[1,2], Prof Kenneth Nordsieck[3]

[1]SAAO. [2]SALT. [3]University of Wisconsin-Madison

Abstract

The Robert Stobie Spectrograph (RSS) is an imaging spectrograph designed to occupy the Prime Focus Instrument Package of the Southern African Large Telescope (SALT). Grating spectro-polarimetry, 3200 - 9000 Angstrom, with resolution R up to 10 000, is always available, using rotating half- and quarter waveplates near the telescope focal plane and a calcite mosaic beamsplitter in the collimated space. In this talk we describe improvements made to the polarimetric calibration to correct for an unexpected time-dependent position angle ``ripple'' vs wavelength which has been seen in high-precision RSS observations and appears to be due to variations in the pupil illumination during an observation. A new calibration technique, which explicitly models the pupil dependence of the polarimetric sensitivity, has been developed. The net spectral polarization sensitivity vs field of view position (X; Y) and wavelength are computed as the polarization pupil dependence, weighted by the pupil intensity illumination of the observation. For the polarization pupil dependence, degree P and position angle are well represented by a polynomial function of position in the pupil. A pupil intensity illumination model for SALT has been devised, calibrated by twilight observations through a pinhole slitmask grid, observed out of focus. The polarization pupil dependence model has been calibrated using observations of the full Moon through a similar mask, plus a polaroid. The final calibration has been checked using repeated observations of known highly polarized standard stars.

The Future of ALMA: Wideband Sensitivity Upgrade and Next-Generation Concepts

Dr. P. R. Jewell[1], Dr. C. L. Brogan[1], Dr. John M. Carpenter[2], Dr. Sean M. Dougherty[2], Dr. Misato Fukagawa[3], Dr. Alvaro Gonzalez[2], Dr. Bunyo Hatsukade[3], Dr. Elizabeth M. L. Humphreys[4], Dr. Norikazu Mizuno[2], Dr. Maria Diaz Trigo[4], Dr. Martin A. Zwaan[4]

[1]National Radio Astronomy Observatory (NRAO). [2]Joint ALMA Observatory (JAO). [3]National Astronomical Observatory of Japan (NAOJ). [4]European Southern Observatory (ESO)

Abstract

ALMA has made many outstanding scientific discoveries in its first decade of observations, ranging from the detection of galaxies in the very early universe, to unveiling star formation within molecular clouds, to imaging planet formation in circumstellar disks. To continue enabling transformative science, ALMA is undergoing the Wideband Sensitivity Upgrade (WSU), the highest priority in the ALMA 2030 Development Roadmap. This will initially double and ultimately quadruple the observing bandwidth and improve receiver sensitivity, with a profound impact in all science areas. This Partnership-wide initiative entails upgrade of most elements of the ALMA system – receivers, IF switch, digitizer, data transmission system, fiber optics, digital correlator and related infrastructure, data acquisition, data storage and processing software, and multiple control, operations, and user interface systems. The WSU system upgrades are currently scheduled for release in late 2029.

Here, we explore concepts for an ambitious follow-up to the WSU, one that aims to achieve a major increase in spectral line sensitivity through increased collecting area, and higher resolution with longer baselines (both recommendations of the ALMA Development Roadmap). Extraordinary science cases abound for an ALMA with such capabilities, including routine, kinematic detection of proto-planetary bodies and un-lensed observations of early galaxies. Technical implementation options are in the initial concept stage, but could involve larger-diameter antennas at fixed locations. Engineering concepts and science cases will be refined through a series of studies and workshops over the coming few years.

Deriving Star Formation Histories of Galaxies from Spectra with Simulation-based Inference

Patricia Iglesias-Navarro[1,2], Johan H. Knapen[1,2], Ignacio Martín-Navarro[1,2], Marc Huertas-Company[1,2], Emily Pernet[3]

[1]Instituto de Astrofísica de Canarias, C/ Vía Láctea s/n, 38205 La Laguna, Tenerife, Spain.
[2]Departamento de Astrofísica, Universidad de La Laguna, 38200 La Laguna, Tenerife, Spain.
[3]Department of Physics, Faculty of Engineering and Physical Sciences, University of Surrey, GU2 7XH, Guildford, United Kingdom

Abstract

High-resolution galaxy spectra encode information about the stellar populations within galaxies. The properties of the stars, such as their ages, masses, and metallicities, provide insights into the underlying physical processes that drive the growth and transformation of galaxies over cosmic time.

We explore an amortised implicit inference approach to estimate from optical absorption spectra the posterior distributions of metallicities and star formation histories (SFHs) of galaxies, i.e. star formation rate as a function of time. We generate a sample of synthetic spectra to train and test our model in a simulation-based inference workflow using the spectroscopic predictions of the MILES stellar population library and non-parametric SFHs.

We reliably estimate the mass assembly of an integrated stellar population with well-calibrated uncertainties. We then apply the pipeline to real observations of massive elliptical galaxies, recovering the well-known relationship between age and velocity dispersion, and show that the most massive galaxies build up to 90% of their total stellar masses 1 Gyr after the Big Bang. The measurements also agree with state-of-the-art inversion codes, but the inference is performed up to five orders of magnitude faster.

This machine learning-based implicit inference applied to full spectral fitting makes it possible to address large numbers of galaxies while performing a thick sampling of the posteriors. It allows to estimate both the deterministic trends and the inherent uncertainties of the highly degenerate inversion problem, so far inaccessible, dealing with the size and complexity of upcoming spectroscopic surveys such as DESI, WEAVE or 4MOST.

Evaluation of South African Candidate Millimetre Sites for Participation in the Event Horizon Telescope

Mr Senkhosi Simelane[1], Professor Roger Deane[1,2], Professor Athol Kemball[3,1]

[1]University of the Witwatersrand. [2]University of Pretoria. [3]University of Illinois at Urbana-Champaign

Abstract

A significant expansion of the Event Horizon Telescope (EHT) will see the strategic addition of antennas at new geographical locations that will transform the sensitivity and imaging fidelity of this ground-breaking ~ 1 mm interferometric array, particularly for snapshot imaging of Sgr A*. A South African EHT station stands out as a promising geographical candidate, well aligned with the scientific requirements of ngEHT and offering strong synergies with the Africa Millimetre Telescope (AMT) in Namibia by adding a crucial, comparatively short ~1000 km baseline for reliably imaging larger-scale (~200 as) features. We assessed three South African candidate millimetre sites with existing infrastructure using climatological simulations, examining millimetre observing conditions over the past decade. Interferometric simulations of hypothetical future EHT arrays were performed for each candidate site under simulated atmospheric conditions, and evaluated using both observation quality metrics and static and dynamical imaging performance. We find that South Africa has at least two promising sites during the typical April EHT observing window. The model suggests these sites outperform some existing EHT stations for the majority of an average year, especially over the June-August period. This will assist the EHT goal of shadow-resolved imaging of M87* with a monthly rather than annual cadence. The results of the climatological and interferometric simulations collectively underscore the sizable, positive impact of a strategically placed South African EHT station on future EHT scientific objectives, which would build on South Africa's past hardware and software contributions to the EHT Collaboration.

Adaptive optics simulations and test bed alignment for MOAO systems.

Dr. Archita Rai, Dr. Kyohoon Ahn, Dr. Jae Joon Lee

Korea Astronomy & Space Science Institute

Abstract

Adaptive optics (AO) technique has been utilised to improve the astronomical seeing, experienced by the ground based telescopes. The system compensates for the wavefront distortions present due to the Earth's atmospheric turbulence. It is an inevitable part of the standard instrumentation suite for all the leading large optical/IR telescope observatories. A set of deformable mirrors, wavefront sensors, phase screens and detectors are used to restore the image quality to diffraction limited performance. Adaptive optics has slowly emerged itself into a full zoo ranging as, MOAO, MCAO, GLAO, LTAO, eXAO and LGSAO, to cite the main ones utilised at different telescope facilities. These variations arise from the limitations to achieve a perfect image (Strehl ratio : 100%) over a varied field of view.
Simulating the AO system helps us in understanding the performance of the different components and the resultant outcome dependency over each parameter. Adaptive optics simulation includes the simulation for atmospheric turbulence, deformable mirrors, wavefronts, wavefront sensors etc and finally these individual components interact to help us in closing the loop, hence, estimating the image quality PSF iteratively. A test bench of optically aligned components in a proper set up is utilised to validate the different aspects of the AO system. This work shall present the simulation results and test bench set up in detail, leading to a conclusive interpretation.

Mechanical design for the cold optics of NOTT, a nulling interferometer for VLTI

György Medgyesi[1], Andras Peter Joo[1], György Mező[1], Alexandra Mazzolli[2], Colin Dandumont[2], Jérôme Loicq[2], Gert Raskin[3], Marc-Antoine Martinod[3], Romain Laugier[3], Germain Garreau[3], Denis Defrère[3]

[1]Konkoly Observatory, Research Centre for Astronomy and Earth Sciences, Budapest, Hungary. [2]University of Liège, STAR Institute, Liège, Belgium. [3]KU Leuven, Institute of Astronomy, Leuven, Belgium

Abstract

ESO's Very Large Telescope Interferometer (VLTI) has long been at the forefront of astrophysical research and instrumentation. Its new visitor instrument suite, Asgard, representing a leap forward in capabilities, will offer high angular resolution and high contrast imaging. Among its four natively collaborating instruments is NOTT, a nulling interferometer dedicated to imaging nearby young giant exoplanets in the L' band (3.5-4.0 microns), with its cold optics designed to operate at 90K. In this study, we present the first stage of mechanical design for NOTT's cold optics, encompassing the mounting for collimation, polarization, and imaging, along with a preliminary mount design for the detector. One of its main challenges is to ensure optimal alignment at the operating temperature and achieve precise focus at the detector plane. A critical requirement is to avoid stress on optical elements during and after the cooling process, to maintain their geometry within tolerances. Our devised system exerts minimal force to maintain axial alignment of the optics while facilitating necessary adjustments to achieve focal precision at the detector plane.

The Past, Present, and Future of the Submillimeter Array

Dr. Jonathan Weintroub

Center for Astrophysics | Harvard & Smithsonian

Abstract

The Submillimeter Array (SMA) is an 8 element radio interferometer on Maunakea in Hawai'i covering the semi-transparent atmospheric windows between 183 and 420 GHz corresponding to short radio wavelengths above and below ~1 mm. SMA was commissioned in 2003 as the first radio interferometer in this band, a pathfinder for later facilities. The eight 6 meter dishes are reconfigurable on baselines from 8 to 508 meters, corresponding to a finest angular resolution of 0.3 arcseconds. A singularly wide instantaneous bandwidth of 48 GHz is correlated to uniform-across-the band spectral resolution of 140 kHz or 0.12 km/s in the 345 GHz band. SMA observations have been published in over 1000 peer-reviewed papers in science areas ranging from high- and low-mass star formation, astrochemistry, supermassive black holes, evolved stars, planets, protoplanetary disks, nearby/high-redshift galaxies, clusters, and time-domain observation of gamma-ray bursts, supernovae, and tidal disruption events. As an early participant in Event Horizon Telescope (EHT) observations SMA pioneered 1 mm phased array beamformer VLBI processing, and become key to the black hole images of M87 and SgrA* published between 2019 and 2022. The SMA plans to upgrade to still wider bandwidths, implementing simultaneous observation in additional frequency bands, and to add solar robustness for direct observations of the Sun's chromosphere. I will discuss the history of the SMA, its current status, and its bright panchromatic future.

Presented on behalf of the Submillimeter Array Team.

MeerKAT: A Giant African Eye and Ear on the Universe

Prof Roger Deane

University of the Witwatersrand / University of Pretoria

Abstract

The 64-antenna MeerKAT radio interferometer, a precursor to the Square Kilometre Array, has amassed a broad range of world-leading results in a short space of time. The coherent confluence of a strategic vision, engineering excellence, and a pioneering human capacity development programme has delivered a state-of-the-art telescope and a diverse community of young African scientists to unlock its full potential. I will give an overview of some of the scientific highlights achieved thus far, from a transformed view of the centre of our Milky Way to the deepest extragalactic radio fields at ~1 GHz; lifting the veil on a diverse population of neutron stars to galaxy clusters; mapping out never-before-seen morphological features in nearby galaxies, relativistic jets from Galactic and extragalactic black holes, to detecting the most distant HI sources and OH megamasers known. MeerKAT's sensitivity and novel backend design have rendered a facility particularly adept at a wide range of time-domain research, which includes the ongoing characterisation of the stochastic gravitational wave background and the search for intelligent life beyond Earth. MeerKAT is demonstrably a transformative facility with an already rich scientific legacy ahead of its incorporation into the Square Kilometre Array, which will also serve as a nucleus for cm-wavelength long-baseline interferometry on the African continent, and beyond.

Status of the Lunar International Observatory

Steve Durst

ILOA

Abstract

The International Lunar Observatory Association (ILOA) is an interglobal enterprise incorporated in Hawaii as a non-profit in 2007, to help realize the multifunctional International Lunar Observatory for long-term astronomy, science and exploration at the Moon South Pole, and to participate in human lunar base. At the time of writing this abstract, ILOA has received the first moon surface and lunar descent images from ILO-X. The ILO-X payload includes a miniaturized dual-camera wide and narrow field-of-view lunar imaging suite. In this contribution the status of ILO-X and ILOA plans for the future will be presented.

Geospatial modeling of a 132kv electricity lines along Alaska_karoi

Geospatial modeling of 132kv electricity line along Alaska_Karoi Tapiwa wallace Gara

Chinhoyi University of Technology

Abstract

This study contributes to the knowledge gap that exists on the use of 3D GIS in transmission line design and electrification. GIS techniques enable the design of a power line in three dimension format and mapping of the existing demand of electricity and. The study also aims to identify the effectiveness of the technique in reducing costs that will be incurred to carry out the project, by identifying optimal routes after considering several factors simultaneously for example land cover and slope , geological characteristics of an area and vegetation cover. In this study we compared GIS with the drawing office techniques and deduce most effective and efficient method. Due to the due to the use of traditional methods of planning and monitoring electricity power lines which results in increased project operation time and more resources , 3D GIS represent viable alternative to meet the increasing demand for energy in the future attaining sustainable development goal number 7.

Poor work efficiency and the ease to optimize a line route continues to be not only a technical issue but a social issue.The motive of this study is that there is need for improvement of the management of the distribution grid and the development of the technique we also realize the limitation of the old distribution grid management systems Therefore, a 3D model for route optimization as a geographic model must be implemented where the terrain and elevation are accurately reproduced

Direction-Dependent Continuum Subtraction in the uv-plane

Dr Sphesihle Makhathini

University of the Witwatersrand. Rhodes University

Abstract

In radio interferometry, {\it continuum subtraction} involves the estimation of the residual continuum emission not captured in the final self-calibration sky model. In the uv-plane, this is done by fitting a smooth function along the frequency axis for each baseline. This approach works very well close to the phase tracking centre (PTC) but gets increasingly inaccurate with increasing distance from the PTC due to chromatic aberration. This work employs a direction-dependent approach to estimate the baseline spectra for multiple directions (or PTCs). Our approach comes in two flavours. The first, segments the field into a regular grid with the directions corresponding to the centres of each segment (akin to image faceting). The second approach uses a brightness-based Voronoi tesselation to determine the segments and directions. In both approaches, the residual visibilities from a given set of directions are combined using appropriate weights to form a final continuum subtracted visibility data set. Preliminary results show an improvement of $\approx60\%$ at the edge of the MeerKAT field of view (Primary beam FWHM) compared to traditional methods ({\tt CASA's mstranform} tool).

FiberPol-6D: Spectropolarimetric Integral Field mode for SAAO 1.9 m Telescope using fibers

Dr Siddharth Maharana[1], Dr Sabyasachi Chattopadhyay[1], Prof Matthew Bershady[2]

[1]South African Astronomical Observatory. [2]Univ. of Wisconsin-Madison

Abstract

Optical spectropolarimeters built to date operate as long-slit instruments, and inefficient for observations of extended objects such as galaxies. 2D spectropolarimetry is a major challenge in astronomical polarimetry .

At SAAO's FiberLab, we are developing a spectropolarimetry capable Integral Field front end called FiberPol(-6D) for the existing SpUpNIC spectrograph on the SAAO's 1.9 m telescope. SpUpNIC is a general purpose 2 arc-minute long-slit spectrograph with a grating suite covering the wavelength range from 350 to 1000 nm and at spectral resolutions between 500 and 6000. FiberPol generates 6D observational data: x-y, wavelength, and the three linear Stokes parameters I, q and u.

FiberPol is a low-cost technology demonstrator (< 10,000 USD), and the entire system predominantly employs small size (1 inch or less), commercial off-the-shelve optics and optomechanical components. FiberPol can be modified for use on any existing spectrograph, especially on bigger telescopes like the 10 m South African Large Telescope (SALT) and the upcoming 30 m class telescopes. Polarimetry is often relinquished on large telescopes due to the requirements of large, expensive and fragile optics, and challenging optical designs. FiberPol opens up the possibility of using relatively small, inexpensive fibre-fed polarimetric units, mitigating all the above mentioned hassle.

The instrument design has been completed. The lab assembly and characterization is ongoing and is expected to be completed by July 2024 with subsequent on-sky commissioning in second half of 2024. In this talk, we will present the scientific goals of FiberPol, its overall design and results from the lab characterization experiments.

A MeerKAT+ and SKA-MID interferometric simulator

Mr Galefang Allycan Mapunda[1], Professor Roger Deane[1,2], Doctor Sphesihle Makhathini[1]

[1]University of the Witwatersrand. [2]University of Pretoria

Abstract

The development of interferometric algorithms and software tools becomes increasingly important with ever larger arrays with increased complexity. These tools aid in the design, and simulation of interferometric arrays as well as data reduction. Despite significant advancements in interferometric data processing techniques, challenges persist in processing data from wide-bandwidth heterogeneous arrays, exemplified by the transition from MeerKAT to MeerKAT+ and then the Square Kilometre Array mid-frequency array. This project will build an end-to-end interferometry simulation software tool and calibration pipeline for heterogeneous arrays such as MeerKAT+ and SKA-MID. Application of this tool include sensitivity calculations, source confusion estimations via synthetic radio source population simulation, as well as to optimise potential sub-array, or the sequential commissioning of receivers within the larger SKA1-MID array configuration. This approach enables the prediction and evaluation of array performance metrics such as; uv-coverage, dynamic range, imaging fidelity, and sensitivity and aid in maximising the scientific utility of future heterogeneous arrays. Additionally, I aim to incorporate VLBI simulations with new stations in African partner countries to assist the expansion of VLBI on the continent.

PASIPHAE: Large optical polarization sky survey for dust cloud & magnetic field tomography using WALOP instruments

Dr Siddharth Maharana[1], Prof Konstantinos Tassis[2], Prof Ramaprakash Anamprambu N.[3]

[1]South African Astronomical Observatory. [2]Institute of Astrophysics, FORTH, Greece. [3]Inter-University Center for Astronomy and Astrophysics

Abstract

PASIPHAE (Polar-Areas Stellar Imaging in Polarization High Accuracy Experiment) project, scheduled to start in late 2024, aims to create the first large stellar polarization map of the sky, spanning thousands of square degrees in the galactic polar regions. This new catalog will enable creation of magnetic field and dust cloud tomography map of the galactic polar regions using stellar polarimetry and GAIA stellar distances as tools. Two WALOP (Wide-Area Linear Optical Polarimeter) instruments, to be mounted on 1 m class telescopes in South Africa and Greece are being developed to measure the linear polarization of stars up to 16 magnitude in SDSS-r broadband with 0.1 % accuracy.

WALOPs have been designed to operate with the combined capabilities of one-shot linear polarimetry, low polarization systematic (< 0.05%) and a large field of view of 35× 35 arc-minutes, making it a unique astronomical instrument. In a single measurement, WALOPs can measure the linear Stokes parameters I, q and u in the SDSS-r broadband and narrowband filters between 500- 700nm. For each exposure, four images of the full field corresponding to polarization angles of 0, 45,90 and 135 degrees will be generated and by carrying out differential photometry on these images, the Stokes parameters can be obtained.

The unique goals of the instrument place very stringent systems engineering goals, including on the optical, polarimetric, optomechanical, and electronic subsystems, all of which have been met.

In this talk, we will present an overview of the PASIPHAE survey, the WALOP instruments and the their current status.

Big Data and Open Science and Engagement in Radio Astronomy

Professor Russ Taylor

University of Cape Town. University of the Western Cape. Inter-University Institute for Data Intensive Astronomy

Abstract

Current and next generation radio telescopes on the pathway to the SKA are driving a tremendous challenge of big data in astronomy and changing the sociology of the scientific enterprise. Key science programs generating massive data sets are being executed by large internationally distributed collaborations. A prime example is the South African MeerKAT large survey projects, which dedicate thousands of hours of time undertaking high priority science programs by teams of senior researchers, postdoctoral fellows and graduate students from across Africa and the globe. This mode of science presents challenges for distributed collaborative research, data access, data analytics, data visualization, and interoperability with distributed multi-wavelength data archives.

Deployment of data intensive cloud systems along with the Virtual Observatory services offers a mechanism to address these challenges. Such platforms also provide outstanding opportunities for outreach and training to disadvantaged regions where access to data and resources is limited. I will discuss the nature of these challenge and approaches under development at the South African Ilifu data intensive research cloud facility developed and operated by the Inter-University Institute for Data Intensive Astronomy.

Future Egyptian 6.5 meter multi modes Telescope: basic design, scientific goals and accessories

Prof Nasser Ahmed

National Research Institute of Astronomy and Geophysics (NRIAG), Egypt

Abstract

Future Egyptian 6.5 M optical Telescopes is a new project instead of old Kottamia observatory (1.8 M, 1962). It will be multi-modes Telescope for a broad range of scientific applications. One mode for photometry, spectroscopic and polarimetry of any stellar objects. Anther mode is corrected focus 1º-3º field of view, for wide field applications such as survey and near earth objects studies.
The basic optical design is Gregorian Nasmyth focus with adaptive optics secondary. The telescope primary mirror is an **f/1.25 honeycomb** of borosilicate glass similarly to MMT and Magellan telescopes. The new telescope will be provided with powerful scientific instruments for high resolution and multi-slits spectrographs.
Polarimetric imaging and spectroscopic will be considered also.
Finally, we are welcome with any astronomical community suggestions.

NRT: observing the transient Universe with the world's largest robotic telescope

DR. Carlos Gutierrez

Instituto de Astrofísica de Canarias. University of La Laguna

Abstract

The New Robotic Telescope (NRT) is an international initiative to build a 4-metre robotic telescope. With a primary mirror consisting of 18 segmented hexagonal mirrors and a control system that will allow fully autonomous operation, NRT will be the world's largest robotic telescope. This, together with a response time of less than 30 seconds, a suite of simultaneously mounted instruments covering the usual modes of photometry and spectroscopy in the optical and near-infrared ranges, and the exceptional conditions at the Roque de los Muchachos observatory (La Palma, Spain) will make NRT a key astronomical facility in the field of time-domain astronomy. The project is in the final stages of design. In this contribution we present an overview of the project and the plans for its construction and operation.

ASTRONOMY AND SPACE SCIENCE FROM THE MOON : PAST EXPERIMENTS AND CURRENT PROSPECTS

Prof Bernard Foing

CEO LUNEX, EuroSpaceHub, Prof Leiden Observatory

Abstract

The Moon is a special platform for astrophysics and cosmology (Foing et al 1993) .

From the Moon one can conduct observation of Earth and environment , as well as planets and solar system objects, in a large range of wavelengths.

Solar observations can be conducted in optical, UV, X-rays, radio, plasma sensors to monitor activity, flares and coronal mass ejections. We shall show some solar measurements from SMART1 and recent missions, and will discuss what could be done from networks on surface and orbit, and peaks of eternal light.

The Moon can host as well small telescopes (including simple transit telescopes scanning the sky over a lunar rotation) to monitor multiwavelength variability of stars and cosmic objects.

Larger telescopes can be used for diverse galactic and extragalactic research, and liquid mirror telescopes can be deployed with a sensitivity beyond JWST.

Interferometric telescopes can also be installed and operated thanks to the high stability and low seismicity of the Moon.

Networks of radio telescopes can be deployed on lunar farside for galactic and extragalactic studies, and cosmology of the dark ages.

The Moon surface can be used also for ultra high energy physics and astrophysics, with the possibility to detect cosmic rays, but also Cerenkov radiation of from subsurface soil of particles up to 10E20 eV .

We performed some precursor tests of lunar telescopes or radio antenna with analogue astronauts during LUNEX EuroMoonMars field campaigns . We deployed a network Low Frequency radio antenna during Etna DLR/ESA ARCHES campaign in June 2022.

From Barriers to Blastoff: Democratizing Space Education in Ethiopia with ESSS Learning

Mr. Lealem Kinfe

Ethiopian Space Science Society

Abstract

ESSS Learning emerges as a pioneering initiative by the Ethiopian Space Science Society (ESSS), destined to redefine the landscape of space science education in Ethiopia. Positioned as a beacon of knowledge, accessible at learn.ethiosss.org, this platform represents a transformative leap for students, instructors, and administrators.

The unique significance of ESSS Learning lies in its mission to democratize space education in Ethiopia. Notably absent from elementary and high school curricula, space science has been a privilege for a select few. As the project manager, my vision is to bridge this educational gap, making space science accessible to every corner of Ethiopia.

By leveraging ESSS Learning, students across the country will gain entry into a realm of knowledge previously reserved for a limited audience. This platform acts as a catalyst for inclusivity, ensuring that space science education is not confined to the privileged, but becomes a shared asset for all. In navigating the intricacies of project management, my aim is to create a user-friendly, intuitive interface that transcends barriers, making it seamlessly available to learners regardless of their geographical or socio-economic background.

As we progress towards the project's completion, the goal is not merely the creation of an educational platform but the empowerment of an entire nation through the democratization of space science knowledge. ESSS Learning aspires to be a catalyst for change, fostering a culture of curiosity, scientific exploration, and inclusivity in the pursuit of knowledge about the cosmos.

Open Science at NASA

Dr. Steven Crawford

NASA

Abstract

Open Science is the principle and practice of making research products and processes available to all, while respecting diverse cultures, maintaining security and privacy, and fostering collaborations, reproducibility, and equity. NASA has long embraced open science in its mission and openly sharing its scientific discoveries with the world. With the Open Source Science Initiative, NASA is implementing the ambitious, open science vision outlined in the NASA Science Mission Directorate's "Strategy for Data Management and Computing for Groundbreaking Science 2019-2024." OSSI includes the recently updated Scientific Information Policy (SPD-41a) that includes updated requirements, compliant with the recent OSTP memo on " Ensuring Free, Immediate, and Equitable Access to Federally Funded Research", for sharing data, publications, and software produced from SMD's research activities. The Initiative further aims to increase accessibility, inclusion, and reproducibility in Earth and Space Sciences through a range of activities including training in open science, development of Open Science technologies, and grants to support Open Science. NASA's Transform to Open Science, a program to train 20,000 scientists over the next 5 years in Open Science and broaden participation from historically excluded groups, kicked off with the US Federal Year of Open Science in 2023. The latest developments include a range of new infrastructure to support open science including the Science Discovery Engine, the Science Explorer, and new capabilities in machine learning and science platforms. These efforts will ensure the next discoveries from NASA science is even more accessible, inclusive, and reproducible.

Incorporating Ionospheric TEC predictions as sensory information for MeerKAT

Ms Lebogang Lekganyane

Rhodes University

Abstract

The ionosphere represents a region in Earth's upper atmosphere characterized by charged particles. Total Electron Content (TEC) gauges the concentration of these particles within a vertical atmospheric column. This project concentrates on incorporating TEC forecasts as sensor information to mitigate the effects of disruptions caused by the ionosphere on radio signals.

Meerkat heavily relies on radio signals for its observations, but the ionosphere can modify their polarization, posing challenges to data precision. To comprehend the ionosphere's impact, the initiative leverages Meerkat's capacity to analyze Radio Interference Data Exchange Format (RINEX) data obtained from on-site servers. A distinctive method involves using the Moon as a calibration tool, exploiting its consistently linear polarization unaffected by the ionosphere. Examining the Moon's radiation refracted through its surface allows for the isolation of ionospheric effects.

The primary objective of the project is to evaluate the accuracy of vertical TEC (vTEC) predictions. These predictions hold promise as corrections for Meerkat's polarimetric observations. A crucial step involves comparing vTEC measurements with data from the Global Navigation Satellite System (GNSS). This forms the foundation for a dependable RINEX-file processing system, offering precise rotation corrections for the astronomy community.

Calibrating the clock of JWST to sub-second accuracy

Aarran Shaw

Butler University

Abstract

JWST, despite not being designed for observing high time-resolution phenomena, can be an unparalleled tool for such studies, opening wide the sub-second infrared timescale regime, if timing systematics can be controlled. Rapid time-domain studies, such as lag measurements in accreting sources and Solar System occultations, require both precise inter-frame timing and knowing when a time series begins to an absolute accuracy significantly below 0.5 s

We present here results from our JWST clock calibration program. We observed ZTF J153932.16+502738.8 - a double white dwarf system that eclipses on a period of 6.91 minutes - over two ~9hr epochs with JWST's NIRCam. The well-known ephemeris of ZTF J1539 allows us to compare the expected time of the eclipses with the actual eclipse times as measured by JWST, providing us with strong constraints on the accuracy of JWST's clock.

Examining Cyber-relevant Cognitive Vulnerabilities and Their Impacts on Protecting Space Systems from Cyber Attacks

Professor Lori Coombs

Marymount University. (NASA) National Space and Aeronautics Administation. University of Arizona Global Campus. WWCM. WWCM Academy. U.S. Senate

Abstract

This focuses on emerging enabling technologies that implicate cybersecurity by identifying the impacts of cyber-relevant cognitive vulnerabilities to develop Cyberpsychology-informed Defenses (CyphiDs) to enhance design processes, harden space systems and increase cybersecurity posture against cyber-attacks. Research may lead to a quantum mechanics approach to support understanding human behavior for developing probability-based decision models that produce Adaptive Psychological-informed Defenses (APhiDs) which can automate the CyphiD sequences. Cyber deception is a defensive technique that considers human factors and the components of a cyber-attack. Deception aims to make it more difficult for bad actors. Experiments will be conducted in a three-phase approach that creates a new cyber research dataset for shared use that can support new human-focused research for the academic and science communities. The Theory Planned Behavior approach will be leveraged on understanding human factors that determine behaviors and decision-making processes. The Grounded Theory approach used to create cyber-specific computational cognitive models (C3M) that reflect and predict attacker behavior based on grounded data that has been systematically collected and analyzed to develop CyphiDs. CyphiD research data developed from open science info shall provide solutions for the evolution of the digital roll-out that considers software sustainment that has evolved to incorporate continuous engineering, which lies at the intersection of fixing problems and providing new capabilities made possible by new hardware and/or new threats that demand new functionality for space systems. The goal is to understand the cognitive vulnerabilities and behavior to advance the science of cyberpsychology and research to support astronomy assets.

Extending the Event Horizon Telescope to Space: The Black Hole Explorer

Dr Jonathan Weintroub

Center for Astrophysics | Harvard & Smithsonian

Abstract

The Black Hole Explorer (BHEX) is a space mission aiming to discover and measure a black hole's photon rings. BHEX captures light that has circled a black hole anywhere from half an orbit to multiple complete orbits. A series of ever sharper photon rings, produced from light that has orbited the black hole increasingly more times before escaping, lie under the Event Horizon Telescope (EHT) ring images. Photon rings require extremely fine angular resolution that can only be achieved by extending the EHT array into space. The physical properties of the black hole are imprinted on the size and shape of the photon ring, creating a new window into relativistic physics. This talk will summarize the primary BHEX science goals and discuss the technology and instrumentation being developed to make the mission a reality within the next decade.

This talk is presented on behalf of all the members of the Black Hole Explorer Team.

The Next Generation Transient Follow-Up Ecosystem

Prof. Andy Howell

Las Cumbres Observatory. University of California, Santa Barbara

Abstract

I will talk about a set of tools to enable rapid follow-up of transients, especially in the multimessenger domain. These include the Target and Observation Manager (TOM) Toolkit, the Hopskotch/HERMES messaging system, and the Treasure Map. The TOM Toolkit lets users trigger telescopes from a web interface. The system also reduces and manages data, and displays it for a collaboration, allowing them to comment on it and manipulate it. Hopskotch is a Kafka-based messaging system that allows uses to send machine- and human-readable messages rapidly and robustly. It is used by the LIGO/Virgo/Kagra collaboration (and others) to send alerts. HERMES is a web-based front-end for Hopskotch, which can submit and receive messages, and provides standards for machine readability. Finally, Treasure Map is a database, API, and visualization that allows users to submit planned and executed telescope pointings for gravitational wave follow-up localization. Users can see these telescope pointings on a visualization overlaid on sky survey data, and adjust their follow-up prioritization based on what others are doing. All of these tools interoperate, so that, for example, users may use their TOM to share send their telescope pointings to the Treasure Map. Or they may share data with the click of a button via Hopskotch, which automatically appears on anther user's TOM. I will discuss current capabilities, but also future needs of this transient follow-up ecosystem.

21cm global spectrum measurement on the lunar orbit and Antarctic ice sheet

Dr Fengquan Wu, Professor Xuelei Chen

National Astronomical Observatory, Beijing, China

Abstract

In this talk, I will focus on the recent development of 21cm global spectrum instrument in National Astronomical observatory, Beijing, China, and the effect to unveil the mystery of Cosmic Dark Age and Cosmic Dawn. First instrument is High-frequency spectrometer-the payload of Hongmeng project and its ground testing. Hongmeng project aims to launch satellite array on the lunar orbit to image the whole sky below 30MHz, and obtain global spectrum at 30-120MHz. Second instrument is the global spectrum instrument on Antarctica ice sheet.

The CANDLE Mission: an absolute flux calibration standard stars

Dr. Susana Deustua

National Institute of Standards and Technology

Abstract

Today's networks of standard stars, in principle, trace their calibration to Vega, often using a "daisy chain" approach. Even when these systems have high internal precision, the true uncertainties are dominated by the uncertainty in the historical absolute flux measurements of Vega resulting in a cascade of systematic uncertainty between 100 nm to 2500 nm (and beyond).

The CANDLE Mission is a proposed space observatory that will provide for the first times, hundreds of spectrophotometric standard stars around the sky whose fluxes are directly traceable to the International System of Units meaning there is "...an unbroken chain of calibrations to specified reference standards... "and "... that the uncertainty associated with a measured value or calibration be sufficiently small to satisfy a particular measurement need". I will describe a concept for a space-based project consisting of twin satellites, each consisting of a telescope and a calibrated artificial star, that can be deployed to establish an all-sky network of high accuracy, absolute flux standard stars. With NIST calibrated instruments and artificial stars above the earth's atmosphere, we aim to achieve total uncertainties of less than 0.5%, a factor of 5 to 10 times better than the current uncertaties over the VIS/NIR range for stars with a range of spectral types and brightness.

Leveraging Large Language Models for Enhancing Accessibility and Efficiency of Research Discovery in Astrophysics

Rohan Rahatgaonkar

Pontifica Universidad de Catolica

Abstract

Given the amount of new papers are uploaded on Arxiv, it can be hard to keep up with new research in your field or even specific topics.To enhance the accessibility of astronomy and stay up-to-date with the latest advancements, we are introducing an AI-based astronomy newsletter tailored to your specific field of interest. This service provides concise, understandable, and insightful summaries, key takeaways, and links to related articles. Our aim is to promote accessibility to current AI tools available for researchers. Consequently, we also curate a list of services and resources for understanding, analyzing, and discovering scientific literature relevant to your field of interest.

DSA-2000: A novel approach to radio interferometry

Mr Francois Kapp

Caltech

Abstract

The DSA-2000 will be a radio survey telescope and multi-messenger discovery engine. The array will consist of 2000 × 5m dishes, instantaneously covering the 0.7 - 2 GHz frequency range, and span an area of 19 km × 15 km. The instrument will use a radio camera processing system to enable real time imaging, and also be capable of transient search and processing at a wide range of cadences. This approach is enabled by two key technologies, i) low-cost, high performance antennas with an ambient temperature receivers, and ii) a novel digital back-end - the radio camera - that outputs image data in real time. The project requires an industrialized approach to construct and commission 2000 antennas in a remote valley in Nevada, shielded by mountains from terrestrial radio frequency interference. Prototype antennas have been built and tested at Caltech's Owens Valley Radio Observatory as the team prepares for construction.

The Hubble Space Telescope: A New Era of Discovery

Dr. Jennifer Wiseman

NASA Goddard Space Flight Center

Abstract

The Hubble Space Telescope has served as the world's preeminent flagship space observatory for 34 years. Hubble is even now at the peak of its scientific power and demand, thanks to innovative uses and multiple astronaut upgrade missions. What is Hubble's role now, as we enter a new era of international astrophysical facilities and priorities? This overview talk will emphasize the unique future role of Hubble in terms of its *capabilities, complementarity,* and *scientific priorities. Capabilities:* The Hubble Space Telescope will serve as a critical and unique UV and optical space platform in the coming years. The outlook for its technical health will be discussed. *Complementarity:* The new confluence of flagship space telescopes together spanning wavelengths from gamma-ray to mid-IR, including e.g. Webb, Roman and GAIA, with precision ground-based platforms like ALMA, SKA, ELTs, and gravity wave detectors, and with solar system probes, will enable powerful new complementary investigations with Hubble in all fields of astrophysics. *Scientific Priorities*: Hubble's future observing program will emphasize its unique role in the highest priority science areas, including time domain and multi-messenger (TDAMM) astrophysics, exoplanet characterization, and the impacts of dark matter and dark energy in cosmic evolution. Hubble's robust archive is also enabling study of transient phenomena that span decades. Hubble will continue to pioneer processes that increase fairness and inclusion in observing proposal solicitations and selections, empowering science for the mission and its worldwide users. Hubble is a direct precursor mission to the Habitable Worlds Observatory, in terms of wavelength bands, science, and user community.

Development of Wideband Antennas

Dr. Hideki Ujihara, Dr. Hideyuki Nosaka

Ritsumeikan University

Abstract

After development of 3.2 - 16 GHz wideband feed for NICT Kashima wideband VLBI project Gala-V which used Kashima 34 m antenna and two portable VLBI 2.4 m stations, development of 16 - 64 GHz wideband antennas and feed systems was started. That can measure water vapor distribution with fine time and spacial resolutions and enable simultaneous VLBI observation. This system has larger bandwidth than conventional water vapor radiometers and can observe Oxygen and cloud emissions to reduce errors in estimation of water vapor in the atmosphere. The system will be tested as a wideband feed system of large radio telescopes, portable 900 mm or 2.4 m stations. Thus the feed can have wide variation of its beam width, from narrow beam for Nobeyama 45 m to wide beam for VGOS or SKA optics. Also they can make flat beam in some frequency range. Development of this system and other technical challenges such as high frequency phased array feed for 100 GHz or more will be presented. These developments are also useful for 6G communications. These works are supported by JSPS KAKENHI grant 21H04524, 23H00221 and NICT fund JPJ012368C04901.

Application of anomaly detection to MeerKAT radio data using machine learning techniques

Dr. Hanwool Koo, Dr. Michelle Lochner

University of the Western Cape

Abstract

As a mid-frequency Square Kilometre Array precursor, the MeerKAT radio telescope is a promising source of large sets of radio data. Developing an automated method for anomaly detection is becoming essential to discover more unknown phenomena for astrophysics or cosmology from the data with such an enormous volume. To do this, we explore anomaly detection techniques for time-frequency dynamic spectra of the radio data. We apply unsupervised machine learning techniques, coupled with active learning, for anomaly detection and evaluate our method using the simulated Single-dish PARKES data sets for finding the uneXpected (SPARKESX). We use these simulations to test anomaly detection methods that will be applied to real, unlabeled MeerKAT data. We also examine the possibility of detecting and removing anomalous radio frequency interference, which acts as the primary contaminant when hunting for genuine anomalies. We expect that applying machine learning methods will be a more efficient and reliable way to detect anomalous astrophysical signals with higher accuracy and in a shorter time than the classical methods.

65 years of Radio Astronomy in South Africa: from The Shack to SKA-Mid

Justin L. Jonas[1], George D. Nicolson[2], Pontsho Maruping[2]

[1]SKAO/Rhodes University/SARAO. [2]SARAO

Abstract

There has been an exponential growth in Radio Astronomy in South Africa over the past two decades, driven primarily by participation in the international Square Kilometre Array (SKA) project. In this paper we present the genesis and development of Radio Astronomy in South Africa (and the African continent) since its origin in the 1950s. The path from humble beginnings to becoming a major contributor to, and participant in, global Radio Astronomy has various enablers, including serendipity, opportunity and strategy. The hosting of the SKA-Mid telescope and the success of the MeerKAT precursor telescope are the most prominent landmarks on this path, but these outcomes were predicated on the foundation provided by the existing modest (but niche) Radio Astronomy activities at the Hartebeesthoek Radio Astronomy Observatory (HartRAO) and some South African universities over many decades. More recently, the expansion has been underpinned by programmes to grow a young and diverse cohort of scientists, engineers and technicians, to recruit industry as technology development partners, and to extend the footprint of Radio Astronomy into the larger African continent. We present a succinct narrative of this history of Radio Astronomy in (South) Africa, from the first observations of Solar radio emission made at Rhodes University in 1958 through to the unprecedented scientific results that MeerKAT is delivering today. We explore this history via the themes of socio-political context, strategy, science, technology and human capital development.

Artificial Intelligence in Astronomy: Unraveling variable stars with machine learning and the NASA Kepler and TESS space missions

Dr Jeroen Audenaert

MIT Kavli Institute for Astrophysics & Space Research, Massachusetts Institute of Technology, Cambridge, MA, USA

Abstract

Astronomy is entering the era of big data through the continuous delivery of millions of observations by both ground- and space-based observatories each day. These massive data sets provide us with a unique opportunity to probe the Universe on an unprecedented scale. The brightness observations of stars delivered by space missions contain a wealth of information for stellar variability, exoplanet and asteroseismology studies. We therefore developed an automated machine learning framework to classify the stars that are being observed by NASA's Transiting Exoplanet Survey Satellite (TESS) according to their stellar variability types, and in preparation for the upcoming ESA PLAnetary Transits and Oscillations of stars (PLATO) mission. Our classifications will form the basis to select the large samples of asteroseismic pulsators required to constrain stellar structure and evolution models. The photometric observations of these large samples of pulsating stars can be then coupled with their spectroscopic observations from ground-based surveys to start unraveling the interior physics of stars with machine learning.

Cultivating Local Wisdom in Astronomical Education for Inclusive Cosmic Exploration- Policy Review in South African Higher Education

Dr Zukiswa Roboji

Walter Sisulu University

Abstract

Global integration of astronomical knowledge fosters cross-cultural understanding, and universal education accessibility, environmental awareness for sustainability. The African continent's situation varies widely across its diverse countries and regions. In the expansive realm of South Africa's higher educational cosmos, astronomical policies face intricate challenges. Within the astronomical educational cosmos, a critical void persists, marked by a lack of inclusivity in existing policies. The problem at hand lies in the failure of current educational frameworks to transcend language barriers, acknowledge diverse cultural perspectives, and cater to the accessibility requirements of differently-abled individuals. This gaping cosmic rift inhibits the full participation and engagement of aspiring astronomers from varied backgrounds. This paper delves into the specific celestial dynamics of South Africa's higher educational system, probing the efficacy of existing astronomical policies in addressing issues of linguistic diversity, cultural resonance, and accessibility for differently-abled learners. By adopting the literature review, the research aims to bridge the gap between traditional astronomical knowledge and formal education, fostering a harmonious and inclusive approach to cosmic exploration within local communities. Cross-referencing information from different sources will be adopted to ensure a well-rounded understanding of the current situation. This review will unearth insights that propel South African higher education toward fostering a more inclusive and culturally resonant cosmic exploration for aspiring astronomers.

Cultural Astronomy in Uganda - Perspectives of Major and Minor Ethnic Groups

Dr Bosco Oruru

Makerere University

Abstract

Uganda has a long history of organized ethnic groups and cultures. Cultural astronomy in the country has been explored very recently. At least twelve ethnic groups have been explored, covering all the four broad linguistic categories of Bantu, Luo, Ateker and Sudanic people. The exploration of cultural astronomy with major and minor ethnic groups, gives a wide range of perspectives in the subject and sets a baseline for exploring cultural astronomy in other African countries. A qualitative research design was adopted, and data were collected with mutual consent by the respondents, who were purposively sampled because they had relevant information. The respondents were mainly those aged 40 years and above. The commonly known visible celestial objects, considered unique in characteristics, have been identified. Most natural phenomena involving celestial objects are considered mysterious, yet ethnic groups have attempted to explain them in their own ways. Some phenomena are thought to be caused by the actions of the gods. The results show that cultural astronomy can be a prerequisite for modern astronomy in most African countries.

Ms Dorothy Mlambo

SAASTA. SAASTEC. DSI

Abstract

This abstract digs into the transformative impact of astronomical education facilitated by the Christoph Meyer Maths and Science Center within the disadvantaged communities of the Umkhanyakude district in rural KwaZulu-Natal province, South Africa. The science center serves as a beacon of hope, offering a unique educational experience that transcends socioeconomic barriers and opens new horizons for individuals facing adversity. The narrative unfolds as a journey beyond boundaries, exploring how the cosmic wonders presented at the science center inspire curiosity, foster critical thinking, and ignite a sense of wonder among learners in a region where educational resources are limited. Through tailored astronomical education programs, the center aims to empower individuals, particularly children and youth, providing them with opportunities to dream beyond the challenges of their immediate environment. The Science Center's initiatives, emphasizes the potential to not only impart scientific knowledge but to instill passion for learning and discovery. Its overarching goal is to contribute to the holistic development of disadvantaged communities, fostering a generation of thinkers, dreamers, and innovators who can transcend their circumstances and contribute meaningfully to the broader scientific community. As we explore this journey, the abstract advocates for collaborative efforts to expand the reach of astronomical education initiatives, ensuring that all communities, regardless of their Geo socioeconomic status, can partake in the empowerment that comes from understanding the cosmos. The Science Center stands as a model for inclusive and transformative education, demonstrating how astronomy can serve as a catalyst for positive change in most underserved regions.

Responsible Telescope Siting: Environment, Community, and Science

Dr Ann Thresher[1], Dr Daniel Palumbo[2]

[1]Stanford University. [2]Harvard University

Abstract

Telescope siting has historically relied entirely upon ensuring sites meet the technical specifications required for observation including weather, atmospheric clarity, accessibility, and cost of developing the site. However, astrophysicists have obligations beyond merely the technical. As the field is becoming increasingly aware, telescopes exist within a broader social context, and the choice of site needs to be responsive to ethical, cultural and environmental specifications just as much as technical ones. We need look no further than the ongoing conflict surrounding the Thirty-Meter Telescope on Mauna Kea or the Square Kilometre Array in South Africa to see the importance of this lesson. In recognition of these challenges, the next-generation Event Horizon Telescope (ngEHT) has founded an interdisciplinary Responsible Siting working group that is integrated into the site selection process. This talk will present a formal overview of the ethical challenges of telescope siting, as well as discuss the work being done by the responsible siting group for a proposed site in Wyoming where the ngEHT has been working with local tribes, governmental organisations, and the university of Wyoming to build mutually productive partnerships. This talk also looks at lessons we can learn from parallel scientific fields including synthetic biology, palaeontology, and conservation in order to advance a set of ethical best-practices for astronomy, and consider the fundamental philosophical challenges of building large-scale scientific experiments, particularly in areas of the world with a history of colonial, environmental, and scientific exploitation.

Identification of Ancient Astronomical records in North India.

Professor Naseer Iqbal

Department of Physics University of Kashmir Srinagar India.

Abstract

The subject of Astronomy and Astrophysics explores the understanding of evolutionary histories of the astronomical events happening in day-to-day universe. Starting from the identification of earlier astronomical records up to now the detection of Gravitational waves the subject of astronomy has revolutionized our view of understanding the universe. The study becomes very fascinating when as a present observer we through a light on the past astronomy and come up with exciting results which helps us to discuss the broader view of different kinds of past records like identification of ancient supernova of a star, identification of Kepler's supernova, impact of falling meteorite and having its significant impact on earth. The identification of earlier supernova records and having a survey of many such records worldwide it becomes quite noticeable that the subject of astronomy has really contributed to bringing considerable discoveries in the modern cosmology.

In my talk I will discuss the following:

Earlier astronomical findings / records in North India.

Opening mathematical astronomy by searching for orbital constant that hidden in variable star cylinder on Earth .

Mr. Mulugeta Markos, Mr. Abduselam Mohammed

Dambi Dollo

Abstract

ABSTRACT The study of astronomy is needed to integrate variable star with mathematics and science education. The scope of this study is the mathematical astronomy. The main objective of this project is to find the cylindrical constant of the variable star astrophysics that hidden in the formula of the volume of any spherical objects on the earth: in a case of western Ethiopia. A cylinder is a solid surface generated by a line moving parallel to a fixed line, while its end describes a closed figure in a plane. If r is the radius of the base, h is the height and d is the diameter of the base, then since cylinder is the limiting form of prism, therefore volume and surface area of the cylinder is also calculated by the same formula of prism. In this study we examined the cylinder constant hidden in the formula of the volume of any circular cylinder. Volume of the cylinder = Area of the base x height. $V=\pi r^2 h$. V = CDh/4.The volume of a right circular cylinder is directly proportional to the square of the radius. Generally, the constant is significant in the circular cylinder formula. This Study and digging out the mystery part of a cylindrical coordinate system needed to understand the origin and the nature of celestial (Astronomical) coordinate system that allows Oromo Educators to calculate Oromo Calendar and register it on UNESCO. Keywords: cylinder, height, diameter, circumference, volume, variable constan

Carnarvon Astro Guides: Developing Astro Tourism programs using Indigenous Knowledge systems as a basis.

Dr Anton Binneman

NRF|SARAO. University of Johannesburg

Abstract

This talk will reflect on the Carnarvon Astro Guide Training project that assumes a pivotal role in positively contributing towards the socio-economic landscape of the Northern Cape where the SKA Project is currently being constructed. Crafted with a dual purpose, this initiative

not only seeks to advance Astro-tourism but also serves as a complementary effort to bolster the upcoming Science Exploratorium that will be constructed in Carnarvon. Through a comprehensive approach, the project has successfully achieved all its defined deliverables, albeit with varying degrees of success. Initial insights derived from formal evaluations have already demonstrated a commendable positive influence on the Carnarvon community's development trajectory.

By synergising the allure of Astro-tourism with Local Indigenous Astronomy, and the developmental potential of the region, this project aims to create a sustainable platform that enhances local livelihoods and enriches the cultural fabric. The integration of Astro-tourism with the Science Exploratorium amplifies its importance, forming a holistic engagement model that bridges science, education, and community empowerment. The project's success is underpinned by the achievement of all outlined deliverables, underscoring the commitment to the endeavour’s realisation. While each deliverable has been met, an iterative evaluation process has indicated that further interventions can catalyse and optimise outcomes. These insights underscore the adaptable and evolving nature of the initiative, positioning it for continuous enhancement and enduring impact.

Context and challenges of Astronomy didactics at high school in Cameroon: an approach through the analysis of curricula and activities implemented by CASRO.CASRO (Cameroon Astronomy and Space Research Organization).CASRO link: https://web.facebook.com/profile.php?id=100069872782126

Dr William Christian Tchaptchet Tchaptchet[1,2,3,4], Mr Roland Ndunge[5], Dr Colette Njiki Chatue[5]

[1]MINESEC (Ministry of Secondary Education). [2]CASRO (Cameroon Astronomy and Space Research Organization).and NEAC Cameroon. [3]Member of AfAS (African Astronomical Society).. [4]WAROAD (West African Regional Office of Astronomy for Development) Coordinator. [5]CASRO (Cameroon Astronomy and Space Research Organization)

Abstract

The recent implementation of the Competency-Based Approach in Cameroon's academic systems has led to ongoing changes in curricula. Some disciplines (Mathematics, Physics, Biology, Computer Science, Geology, Geography) are clearly presented in the curricula. However, others, such as Astronomy, are subtly evoked in the curricula or presented by teachers of other disciplines when they address concepts (gravity, Planet Earth and the Solar System, the satellite in robotics/computing, etc.) that are directly linked to them.

Technological developments must inspire the design and implementation of educational programs to encourage learners to take a greater interest in STEM. In Cameroon, the relationship between STEM and Astronomy is still in its embryonic stages. It is influenced by several parameters: teachers' knowledge, pedagogical approaches, students' knowledge and/or conceptions, available materials, scientific approaches and the socio-cultural context. To raise awareness among communities and learners of the importance of STEM for their development, an urgent look needs to be taken at interdisciplinary and practical subjects such as: Earth Sciences, Geography, Astronomy.

The aim of this work is to evaluate the possibilities and advantages of involving Astronomy in Cameroon's high school curricula. Analyses will be carried out in two stages:

1- Present the high school curricula that deal with Astronomy concepts.

2- Propose pedagogical, scientific and cultural approaches and/or conceptions that can enable the evolution of Astronomy paradigm shifts in the high school academic system. An overview of the current implementation challenges of astronomical activities in certain academic and professional institutions will be presented.

Finding the Origin of Circle constant that can open the connection between Ayyaana Observation in the Ayyaantuu's African cosmology and Borena Calendar

Mr. Abduselam Mohammed Yasin[1,2], Mr. Mulugeta Marikos Tediso[1], Dr. Habtamu Fekadu[3]

[1]Dambi Dollo University, Dambi Dollo, Ethiopia. [2]Ethiopian Space Science Society Dambi Dollo Branch, Dambi Dollo, Ethiopia. [3]Walter Sisulu University, Mthatha, South Africa

Abstract

Astronomical STEAMP team of Dambi Dollo University has been investigating variable device of orbital physics (elements) like Namoratonga pillar to interpret the light message of variable stars like Borena Calendar star and Kepler star, since 2020. The team invented variable ring as circle constant device to solve its memorization method problem in present Ethiopian science education. But not published. The educational research report of Yus and Beti (2021) confirmed the presence of the same issue in Indonesia. The modern astronomical research of Borena Calendar revealed that Ayyaantuu is an expert who computes Borena calendar. The uniqueness of the present work is that we investigated the mathematical astronomy of Ayyaana Observation (Success observation) and Borena variable star. The role of Ayyaantuu is not only computing the calendar. Ayyaantuu also forecasts the future opportunity of an interested person by making a proper observation of some materials like a cup of coffee. However, the connection between the astronomy of Namoratonga pillar and the cosmological prediction device was not studied. In this work we have identified that we can also read a circle constant from coffee cup. we measured the circumference and diameter of cups of coffee and orbital ring. The ratio of the first parameter to the second was computed and the contribution of the constant in the mathematics of Borena calendar was discovered. The new finding of this work shows that the indigenous cosmology in Borena calendar allows people to integrate physics and astronomy. Consequently, we will contribute a critical presentation on this issue.

The linkage of Fichee Chambalala Festival with celestial body.

Mr. Mulugeta Markos Tediso

Department of Physics ,Dambi Dollo University, Dambi Dollo, Ethiopia.

Abstract

The fichee Chambalala Festival, a celebration of culture and community,intricately intertwines with the captivating allure of celestial bodies, creating a unique and enchanting experience for attendees.Thefestival's astronomicalcomponent embraces celestial bodies as a profound source of inspiration, providing a platform for stargazing, cosmic storytelling, and astronomicaleducation.By integrating star gazing sessions, celestial photography workshops,and cosmic-themed performances, the festival not only immerses attendees in the wonder of the night sky but also nurtures an appreciation for the interconnectedness of humanity and the cosmos. the festival's celestial linkage extends beyond mere observation, as it serves as an educational window to celestial phenomena, celestial navigation, and indigenous astronomical knowledge. Through the fusion of scientific insights with cultural narratives, the festival honors historicastronomical traditions, offering a unique opportunity to bridge ancient wisdom with modern scientific understanding the Festival's connection with celestial bodies inspires a deeper contemplation of environmental stewardship, as it emphasizes the themes of celestial harmony, cosmic interconnectedness, and the need for preserving natural darkness. This ethos not only underlines the festival's commitment to sustainability but also kindles a sense of responsibility for nurturing both cultural and natural heritage.hence,the Chambalala Festival's meaningful linkage with celestial bodies transcends mere observation, offering a profound celebration of astronomy,cultural diversity, and communal harmony.

After a Decade of Astronomy In Ghana

Dr Naomi Asabre Frimpong[1,2], Dr Theophilus Ansah-Narh[1], Dr Benedicta Woode[1], Dr Emmanuel Proven-Adziri[3], Dr Joseph Tandoh[1]

[1]Ghana Space Science and Technology Institute. [2]African Astronomical Society. [3]Ghana Space Science and Technology Institute/ Ghana Radio Astronomy Observatory

Abstract

Ghana, in collaboration with the Ghana Space Science and Technology Institute, has been an active participant in SKA-SA since 2012. A decade subsequent to the introduction of astronomy in Ghana through the SKA and the conversion of the 32-meter telecommunication satellite into a radio astronomy observatory, it is imperative to assess how Ghana has effectively utilized this remarkable equipment to address the human capacity gap and foster socio-economic development. An examination of the initiatives and activities implemented during the past ten years of astronomy in Ghana offers insights into this transformative journey.

Informal learning programs as a way to enhance astronomic knowledge. Example from Tunisian experience.

Dr Slimene Sedrette, Dr Slimene Sedrette

Ministry of Higer Education and Scientific Research / Monastir Science Palace

Abstract

Nocturnal beauty of the sky and the universe has captivated the imagination of humans since the dawn of time, making it an excellent springboard to interest people in astronomy. While, the lack of astronomy subjects in primary and secondary school curricula still remains a contributing factor to common misconceptions about what are considered fundamental concepts of astronomy.

This contribution focused on the effectiveness of the informal learning programs to enhance astronomical knowledge.

Science centers have played a significant role and still constitute a very significant informal learning sources in astronomy for large public. This public institutions contribute also to improving astronomy education teacher through training programs in order to develop their performance on the one hand, and to create an environment conducive to interactive learning in their own schools, on the other hand.

The astronomical observations and the mobile scientific program which reach poor and needy regions contribute to the dissemination of scientific culture and give remote schools and associations the opportunity to familiarize themselves with the concepts and learning tools of astronomy.

Science Festival and competitions provide an opportunity to show innovations and creations, in order to achieve the desired communication between the various scientific structures and different segments of society.

The existence today of a large number of astronomy associations and clubs in educational establishments, as well as the growing number of students interested in astronomical research areas in Tunisia, could be the result of informal astronomy learning programs that have been operating for almost 30 years.

Urban Astronomy : What can modern space telescopes teach us about the distribution of light in cities ?

Mr Sukuma Mkhize

SKA SA

Abstract

Modern astronomy has evolved far away from developed cities as a result of the city lights that interfere with observations and prevent us from making pristine measurements of the cosmos, what is often referred to as light pollution. The emergence of some of the most spectacular night time-city light images lately with the advent of the international space station should come as a surprise then, since by convention telescopes are meant to be pointed as far away as possible from the city night sky. Almost as surprising is how these images reveal a logic and a labrynth that is ironically only accessible from space using the most precise instruments to pull out individual city light details as well as cover the span of an entire city. Some of the most popular ones to surface from the ISS are those of London, New York, Melbourne, Berlin Johannesburg & Cape Town and will form the basis of the presentation, the question being can we use these images to identify "dark spots" as possible sites for miniature observatories ? Once identified, can some of these dark spots be earmarked and conserved to promote astronomy activities within South African cities ? In this presentation I will also highlight initiatives that are being carried out by the Dark Sky Organisation and similar networks and what lessons can be derived for further promoting astronomy in cities within the South African context.

How Outreach Helped Mozambique Building an Astronomy Community

Prof. Cláudio Paulo

Universidade Eduardo Mondlane, Faculdade de Ciências, Departamento de Física, Grupo de Astrofísica, Ciências Espaciais e Inteligência Artificial

Abstract

Mozambique is one of the African countries partnering with South Africa for the implementation of the Square Kilometre Array (SKA) Initiative in Africa. Since 2004, an effort has been made by a local scientist to introduce Astronomy in the country where outreach played a very good role. Here, we share the struggles and happiness of conducting outreach in a country with limited resources and present the successful results and future aspirations which can be used as a model for Africa Astronomy Development. By using amateur telescopes in public places, schools and universities for almost 20 years it was possible to motivate young people to pursue their careers in Astronomy which brought us some people with PhD Degrees, MSc and PhD students abroad, as well as, a Post Doctoral Fellow in the country which opened a new environment at Eduardo Mondlane University (UEM). The approach itself was vital to attracting external funding (e.g. from the DSI in South Africa, IAU, DARA, and DOPPLER) which was used for the establishment of the Computer Laboratory for Astronomy, Space Science and Artificial Intelligence at the UEM and the High-Performance Computing Facility at a Park of Science and Technology which are being used as the core for the future SKA in the country. Everything done led to the production of a roadmap which outlines the future of the field in the country and enriched the motivational letter to support the Introduction of an Honours Degree in Astronomy at the Department of Physics at the UEM.

2020 Solar Eclipse and the discovery of new single rock building in Africa

Mr. Abduselam Mohammed Yasin

Dambi Dollo University, Dambi Dollo, Ethiopia

Abstract

2020 Solar Eclipse and the discovery of new single rock building in Africa

Abstract

Every new outcome is hidden in the beginning. We have investigated 684 Delta Scuti Kepler Pulsating variable stars, in 2018 at Ethiopian Space Science and Technology Inistitute (the present Space Science and Geospecial Inistitute). Using time delay method called Binarogram we have identified that 106 of them have single companion and 4 of them have two companions which implies that they are a member of the binary and triple star systems respectively. Two years later, in 2020, a solar eclipse happened in many parts of Ethiopia like Lalibela, Korem and Begi. We have observed a total solar eclipse at Lalibela where 11 single-rock building exists. This empowered us to investigate where a partial solar eclipse occurred, called Begi, though Begi community missed visiting it. Fortunately, we have discovered ancient single-rock building and we have offered a scientific name called Keppler Bollo so that it integrates the study of Kepler stars and the 2020 solar eclipse. Dambi Dollo University was also started astronomical research at Kepler Bollo, based on the submitted report of the newly discovered building of ancient World.

Key Words: Solar Eclipse; time-delay; single-rock building; Kepler star; Kepler Bollo

Advancing Astronomy Education in Africa: A Decade of Impact and Future Horizons

Ms Olayinka Fagbemiro

Nigerian Space Agency. Astronomers Without Borders (AWB) Nigeria

Abstract

This paper presents a comprehensive overview of a decade-long initiative dedicated to advancing astronomy education in Africa, with a focus on Nigeria. As an amateur astronomer and longstanding staff of the Nigerian Space Agency, I have been actively involved in spearheading Astronomers Without Borders (AWB) in Nigeria. Our organization, documented at awbnigeria.org, has been at the forefront of creating astronomical awareness and fostering education among diverse audiences, including young people, school children, and out-of-school children.

The outreach efforts detailed in this presentation highlight the innovative approaches employed by AWB Nigeria to engage communities and schools, utilizing the passion of volunteer amateur astronomers. Through a series of workshops, stargazing events, and collaborative projects, we have successfully nurtured a burgeoning interest in astronomy across the nation. The paper will showcase specific instances of impactful initiatives and their outcomes, emphasizing the importance of accessibility, inclusivity, and sustainability in our educational endeavors.

In conclusion, the paper will outline our vision for the future, emphasizing the importance of continued collaboration, technology integration, and policy advocacy to sustain and expand the reach of astronomy education in Africa. As the IAU GA 2024 marks a historic moment on the African continent, this presentation seeks to contribute to the broader discourse on making astronomical science accessible, impactful, and environmentally sustainable in the pursuit of a brighter astronomical future for the continent and its people.

Amateur activities and public Outreach in Nepal by Takshashila Astronomy Club

Professor Jayanta Acharya

Balmikee Campus. Takshashila Astronomy Club founder

Abstract

Takshashila Astronomy Club (TAC) has been dedicated to promoting astronomy in Nepal. The presentation provided an overview of the club's amateur activities and the outreach initiatives undertaken by TAC. Noteworthy events include star parties featuring the participation of the first president of Nepal, as well as regular Sunday sessions where solar observations are conducted using Japanese solar eclipse glasses, involving numerous students.

This paper explain into the methodologies employed by TAC in organizing such activities and sheds light on the challenges faced in Nepal. It aims to showcase the efforts made by the club to popularize astronomy and engage the public, as well as to address the unique obstacles encountered in the pursuit of these goals within the Nepalese context.

Astrotourism in Nepal

Professor Jayanta Acharya

Balmikee Campus

Abstract

Nepal is a small, landlocked country situated in South Asia, positioned between India and China. Renowned for its breathtaking Himalayan mountain ranges, including the world's highest peak, Mount Everest, Nepal also boasts a rich history and cultural heritage, with numerous temples and monuments dating back to the medieval period.

In an effort to foster public awareness and interest in astronomy, as well as to support astronomical research in Nepal, various activities are organized. These include public lectures, workshops, and sky observation sessions, all aimed at promoting the field of astronomy within the country.

Recently, an astrotourism project has been initiated in Nepal with the objective of linking scientific knowledge and information technology with the tourism industry. This paper elucidates some of the distinctive cultural activities associated with astronomy in the context of Nepal.

Key words; Astrotourism, Mountain, Research, Science

Challenges of Astronomy communications in rural communities and academic institutions in Cameroon: an approach through the activities implemented by CASRO.

Dr William Christian Tchaptchet Tchaptchet[1,2,3,4], Mr Roland Ndunge[5], Dr Colette Njiki Chatue[5]

[1]MINESEC (Ministry of Secondary Education). [2]CASRO (Cameroon Astronomy and Space Research Organization) and NEAC Cameroon. [3]Member of AfAS (African Astronomical Society).. [4]WAROAD (West African Regional Office of Astronomy for Development) Coordinator. [5]CASRO (Cameroon Astronomy and Space Research Organization)

Abstract

This work deals with the challenges of astronomical awareness in three rural areas (Dschang in the West, Missolé on the Littiral and Yagoua in the Far North) of Cameroon (a developing country), where communication contexts differ from one area to another and must respect cultural values. The geographical location of these areas has made astronomic communication highly complex. Indeed, these areas have been exposed to rural migration. Over the last 05 years, they have welcomed refugees from crisis zones in Cameroon. This phenomenon has already generated a cultural intermixing that has fragilized many of their traditional cultural values, including the traditional norms of communication that they have long preserved. A serious challenge remains in the cultural acceptability of these rural areas to both modern and international communication standards.

The question is therefore how to find a suitable communication medium that will respect the culture of these communities by showing the importance of Astronomy for their development and accessibility to quality education for all (gender equality and STEM). In this work, we aim to (1) show the importance of Astronomy in Cameroon's education system (in the particular case of secondary school curricula analysis). (2) Highlight the role of academic institutions (teaching staff and learners) and local associations in supporting Astronomy communication. (3) to present the activities carried out by CASRO (Cameroon and Astronomy Space Research Organization) in these regions from 2021 to the present.

Key words: Cameroon; Astronomical communication; Rural area; Developing Countries; Quality education for all; CASRO.

How (not) to write a popular astronomy book

Mr. Govert Schilling

Self-employed

Abstract

Despite the rise of online media, old-fashioned books still constitute an important channel of astronomy communication for a wide variety of target groups, from young children and curious amateur astronomers to highly interested seniors. Many professional astronomers and astronomy popularizers or educators would love to write their own book at some point, but finding the right topic, approach, style and - last but not least - publisher can be hard. Acclaimed and prize-winning Dutch astronomy writer Govert Schilling, who wrote almost 100 books over the past 40 years, shares his personal experiences, provides insight in the market for popular astronomy books, and tells you about the challenges, opportunities and potential pitfalls.

The cultural heritage of the African Arc of the 30th Meridian(Invited Talk Commission C3)

Dr Christiaan Sterken

University of Brussels

Abstract

The African Arc of the 30th Meridian is a chain of survey triangulations stretching from Cairo in Egypt to the southern tip of the African continent, over more than 9000 kilometer through Botswana, Mozambique, Zimbabwe, Zambia, Tanzania, Burundi, Uganda, the Democratic Republic of Congo and Sudan.

The project was initiated in 1874–1876 by Sir David Gill who was in Cairo for the Survey of Egypt, where he, in his own words, "measured a very very accurate kilometre, established the latitude and longitude of the Great Pyramid, and measured the sides and height of the Great Pyramid to ± 1 millim., and their exact azimuths by a triangulation" (1916). Gill's short base line was below and to the south-east of the Sphinx. The material Africa-wide heritage consists of survey beacons, several of which have been declared as national monuments.

The Arc is an outstanding example of a technological ensemble that helped in the establishment of the size and shape of the Earth. It was also an extraordinary example for interchange of human values in the form of scientific collaboration among scientists and political representatives from different countries, and it supplied the natural control for the surveys of Eastern Central Africa. The 30th Arc of the Meridian was 75 years in the making and its implementation was severely hampered by political conflicts and situations of war.

This presentation formulates a case for the Arc of the Thirtieth Meridian as a World Heritage Monument to be submitted to UNESCO for consideration.

Citizen Science: A Tool for Astronomy Education, Dark Sky Protection Awareness, Astro-Tourism Development and SETI

Timothy Egbuim, Dr Bonaventure Okere, Dr Nnaemeka Onyeuwaoma

West African Regional Office of Astronomy for Development (WAROAD), Centre for Basic Space Science and Astronomy (NASRDA), Nigeria

Abstract

The engagement of non-professional astronomers in science through citizen science is a thriving practice that produces new knowledge for science and society. The application of citizen science to astronomy education, dark sky protection awareness, astro-tourism development, and SETI through Vanishing and Appearing Sources during a Century of Observations (VASCO) has been instrumental in space science development in Nigeria. Globally, light pollution of the night sky by artificial light sources has led to a significant loss of the natural skies, which can be attributed to urbanization. To curb the menace of light pollution and promote astro-tourism across Nigeria, this project engages space enthusiasts, space scientists, students, teachers, and scientific groups through workshops, experiments, and group projects. The dark sky protection projects thus far include the use of sky quality meters to estimate brightness levels in various environments, the use of the Globe at Night application to measure night sky brightness, and the use of the Anecdata application, which uses smartphone astrophotography to report light pollution in different communities. Through citizen science, astro-tourism is publicized using formal and informal approaches, especially the need for investments in cultural astronomy, astro-archaeology, and planetariums. The Search for Extraterrestrial Intelligence (SETI) through VASCO citizen science has led to the discovery of various artefacts, galaxies, and meteors. These projects have shown over 70% increased interest in STEM among participants. The scientific gains of citizen science cannot be overemphasized, as it is essential in the evolving world of science. Through these projects, the United Nations SDGs are achieved.

Astronomy for Astronomical Numbers

Professor Chris Impey

University of Arizona

Abstract

The design and implantation of five massive open online classes, or MOOCs, are discussed. These online classes are offered through Coursera and Udemy and they are reaching astronomical numbers of informal, lifelong learners. Over 420,000 people have enrolled from 180 countries. Over 6 million minutes of astronomy video content have been consumed. Two MOOCs are on general astronomy, one is on astrobiology, one covers Biosphere 2 as a model for living off-Earth, and one is on the history and philosophy of astronomy. Online courses for informal lifelong learners address the challenge of delivering engaging astronomy content online to large numbers of people and reaching them in poor or developing countries. Design principles that allow MOOCs to inform and inspire are covered. Challenges include increasing interactivity, which can improve the typically low completion rates. Enrollment surged by a factor of ten during the pandemic and remains well above pre-pandemic levels. MOOCs are centered on a core of video lectures, but to maintain active engagement other elements are recommended, like quizzes, writing assignments, and citizen science projects. Short writing assignments are subject to peer review and recently we have used large language models to grade student assignments and create rubrics. GPT-4 can grade more reliably than peers and it approaches the reliability of an instructor. Live Q&A sessions attract over a hundred participants and thousands of views afterward on YouTube. The broad reach of MOOCs lets them reach relatively isolated and underserved populations.

Digitization and Study of the Ancient Egyptian Astronomical Texts: A Research Project featuring the Lore of African Skies

Dr Dr Alicia Maravelia

Hellenic Institute of Egyptology. Centre for Life-Long Learning-Hellenic Open University

Abstract

DCSAEAT (= *Digitization and Complete Study of the Ancient Egyptian Astronomical Texts*) is one of the Research Projects of the Hellenic Institute of Egyptology, aiming to safeguard, promote and study in depth the pharaonic astronomical and cosmographic lore, pertaining to ancient Northern African Skies. It is performed internationally [Partners: the Institute (Alicia Maravelia) and the Writing & Scripts Centre of Bibliotheca Alexandrina (Ahmed Mansour)], in (voluntary) collaboration with several colleagues and graduate students from Greece, Egypt, New Zealand, Poland and Italy. The AEAT is a corpus of antique and interesting testimonies about the astronomical heritage and knowledge of ancient Egyptian culture, imbued with a strong metaphysical and religious background of cosmic metaphors/allegories, through which important pre– or proto–scientific knowledge was presented and ancient skyscapes were described. Since the eras of the most ancient funerary texts and the «Books of the Hereafter», the Diagonal and Ramesside Star Clocks, various astronomical ceilings in royal and private tombs and temples, zodiacs, calendars, astronomical instruments (including: typical «kits» of ancient priests–astronomers with mrxt and bay n imy-wnwt; clepsydrae; sundials), the accumulation and development of astronomical and cosmographic lore was continuous. The Project aims at the complete and methodological study of all extant AEAT and artefacts, extending the outstanding but outdated work by Neugebauer & Parker [*EAT*], collecting/classifying all modern literature and knowledge, building interactive Database(s), digitizing/reproducing/documenting/cataloging/exhibiting the most important texts, publishing a Series of splendid volumes with rich iconography, and training students to study ancient Egyptian/African sky–lore and heritage.

ASTRONOMY OUTREACHES IN PRIMARY AND SECONDARY SCHOOLS IN TANZANIA

Mr. ELINEEMA NASSARI

Mount Meru Astronomical Observatory

Abstract

INTRODUCTION

Astronomy in Tanzania is not an independent Subject in the curriculum, it just a topic and in some subject is just a subtopic. Some subjects such as Geography and Physics have topics which talks about Astronomy but challenges is that teachers who teaches those subjects are not aware about astronomy at all since they just learn it partially since there is no good foundation of astronomy in the country.

MOUNT MERU ASTRONOMICAL OBSERVATORY

This is a Non Government Organization (N.G.O) Its main function is to inspire students and teachers in Astronomy. MMAO have been able to receive grants from IAU OAD on 2023 for Teachers Training workshop which was tremendously succeeded.

Mount Meru Astronomical Observatory is receiving students and teachers from different schools who visits the observatory for learning purposes. Geography students and teachers came to learn all about solar system by watching different videos about the solar system. This helps student to understand easily their subject.

Astronomy clubs, are groups of students who have been inspired with astronomy. They used their extra time to learn astronomy at their schools and they used also visit other students from different schools to inspire them as well. They usually conduct astronomy exhibition at their schools during graduation and during talent days.

MMAO with ambassadors conducts outreaches to different schools inspiring students and teachers about astronomy and establish new astronomy clubs. Students are so exited with astronomy and loves the subjects since it helped them to ask many questions about the universe.

Unearthing Rich Cultural Astronomy in Ghana

Dr Emmanuel Proven-Adzri[1], Mr Steven, O. Sottie[1], Dr Cyril, D. Boateng[2], Dr Linus,K. Labik[2], Mr Samuel, O. Quarm[2]

[1]Ghana Space Science and Technology Institute. [2]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Abstract

Ghana has a rich and diverse cultural history that spans ancient civilization, colonialism, and independence. Due to the diverse cultural composition of Ghana, many cultures have indigenous traditional practices or observations about astronomy. This project was undertaken to dig out this indigenous knowledge of astronomy and how it affected the daily lives of people in Ghana. Eleven sites were visited across Ghana with remarkable discoveries. The findings point to how astronomy helped the locals to undertake daily activities, including those that are related to their livelihoods. According to these discoveries, hunters, for instance, rely on the direction of Venus to return home when they stray too far when they are out hunting at night. The crescent moon curved upwards may indicate early rains for farmers. The emergence of certain stars on the horizon is a prelude to the harvest of certain fish in the sea. When the Milky Way is spotted sometime in July, it indicates the major rainy season is about to end. In some communities, widowhood rites only occur when the new moon is sighted. The project has interlaced the traditional beliefs of the indigenous people about the cosmos concerning their religion, folklore, fishing, farming and hunting, and art as contrasted to modern astronomy.

Students' International Network for Astronomy and its projects for sustainable development

Mahdi Rokni[1,2], Akihiko Tomita[3]

[1]Associate of IAU Commission C1 WG Astronomy Education Research & Methods. [2]Manager of Students' International Network for Astronomy (SINA). [3]University of Wakayama

Abstract

This network has been established by students in a small city in the south of Iran. It was a desire to globalize all the activities and plans that they have been carrying out in Mehr observatory. Some of these activities contain a lot of social skills and different methods for students to do. The main aims of this network involve students in astronomical programs and projects, preparing a reliable structure for students around the world to meet each other using astronomy as a link, using the methods of sustainable development to teach students about the global environmental concerns and world peace, letting students make friends with each other without limitation and introducing their own culture.

After a long journey with so many students, teachers and astronomers from all over the world specially from Iran, Japan, Thailand, Romania, Bulgaria and Spain. SINA's main activities have been through cultural relations with astronomy and those aspects which contain people lifestyles, such as Persian solstices and equinoxes' celebrations and introducing some scientific projects in order to inform the society about the importance of dark sky protection.

Sensibility of Planetary Defense: Involving Africa in Global Initiatives

Dr. Youssef Moulane

Mohammed VI Polytechnic University

Abstract

The increasing recognition of potential threats posed by near-Earth objects (NEOs) has led to a growing global interest in Planetary Defense initiatives. These efforts aim to identify, track, and mitigate the impact risk of asteroids and comets that could potentially collide with Earth. While this field has traditionally been dominated by space agencies and institutions from developed nations, there is a growing awareness of the need for a more inclusive and collaborative approach, particularly involving regions that have been underrepresented.

This talk explores the sensibility of involving Africa in Planetary Defense efforts, emphasizing the continent's unique contributions and challenges. Africa's diverse geographical locations provide valuable observational perspectives, enhancing the global network for NEO detection and tracking. Furthermore, Africa's burgeoning scientific community can actively contribute to the research and development of technologies for planetary defense.

This talk underlines the need for international collaboration and the establishment of partnerships between African space agencies, research institutions, and their global counterparts. By fostering a sense of shared responsibility in Planetary Defense, Africa can play a crucial role in the collective efforts to safeguard the Earth from potential celestial threats.

Finally, I will advocate for a more inclusive and globally collaborative approach to Planetary Defense, with Africa serving as a significant partner in enhancing our collective capability to detect, monitor, and respond to potential impact threats from space.

Pan-African Citizen Science e-Lab: An Emerging Online Platform for Astronomy Research, Education and Outreach in Africa.

Mr Miracle Chibuzor Marcel

Pan African Citizen Science e-Lab

Abstract

The Pan-African Citizen Science e-Lab (PACS e-Lab) is the leading platform in Africa for engaging the public in citizen science projects related to astronomy. Our activities promote hands-on astronomy activities in Africa to enhance Africans' knowledge and skills in this field. We are a very inclusive and diverse community with a network throughout Africa and beyond. We provide opportunities for African teachers, students, and astronomy enthusiasts to engage in cutting-edge research. The different research activities are:

Asteroid hunting: This activity involves searching and discovering new asteroids from datasets observed with telescopes such as the Pan-STARRS and the Catalina Sky survey. This project also contributes to the planetary defense efforts. Our African teams have made over 30 provisional asteroid discoveries, awaiting further study by the Minor Planet Center and astronomers worldwide.

Exoplanet research: This project is about observing and performing photometry on exoplanets that have already been discovered by the TESS and Kepler missions to refine their Mid Transit Time. This supports upcoming missions like the JWST and the Nancy Grace Roman Space Telescope. We use web telescopes such as the LCO and Micro Observatory for this purpose.

Astronomy Research Writing: This involves conducting research and writing research papers on double stars, variable stars, etc. Our participants are trained on how to use the LCO for data acquisition and different programs to process the data.

Astro Photo Visual Development: this project equips our participants with the skills to process deep-space images from JWST, HST, and the LCO to produce beautiful visuals.

Education in IKI

Andrei Sadovski

Space Research Institute (IKI)

Abstract

The issues of history and organization of interaction between IKI RAS universities and schools are considered. It is worth noting that a scientific organization in Russia is not a university, it has no opportunities to organize teaching.

As for the students the Department of Space Physics of the LFI (Landau School of Physics and Technology) of the Moscow Institute of Physics and Technology (MIPT) exists at IKI. The task of the Department is to train highly qualified specialists engaged in space research using rocket probes, Earth and planetary satellites, and interplanetary spacecraft. For more than 50 years of its existence, the Department of Space Physics has trained more than 400 graduates, of whom more than 150 people work at IKI RAS. In 2016, the Chair of Space Physics was organized at the Faculty of Physics of the National Research University Higher School of Economics. The Chair specializes in training specialists in three main areas: high-energy astrophysics, space plasma physics and solar physics. Around the same time the Department of Remote Sensing Technologies was established at the Faculty of Space Research of Lomonosov Moscow State University. Somewhat later, the educational program "Studies of the Moon and Planets" appeared.

We considered problems and future of such student and pupils training.

World Heritage and Astronomy – Inscriptions and Progress

Professor Michael Burton

Armagh Observatory and Planetarium

Abstract

UNESCO, the United Nations Educational, Scientific and Cultural Organisation, may inscribe sites that are recognised to have "outstanding universal value" world heritage status. Such sites belong to all peoples of the world, irrespective of the territory on which they are located.

Over a dozen sites with an astronomical connection now have such a status. Perhaps the most famous example is Stonehenge, with alignments of rising of the Sun at solstices illustrating humanity's early awareness of celestial and seasonal cycles. The inscription of Jodrell Bank radio observatory in 2019 marked a sea-change in the recognition of world heritage with the inclusion of a modern scientific facility in the list. The heritage being recognised here was the development of radio astronomy itself and the extant examples of this still present at Jodrell.

Since the last IAUGA six further sites with an astronomical connection have been added to the UNESCO list. This presentation will discuss these inscriptions, for instance the Chankillo archaeo-astronomical complex in Peru that functioned as a calendrical instrument, the Paseo del Prado in Spain in which the Royal Astronomical Observatory is sited, and the Eise Eisinga Planetarium in the Netherlands with a mechanical scale model of the Solar System dating from 1774. UNESCO candidature is also being actively pursued for several other sites, notably in Germany, Argentina and Ireland.

Astronomy as a tool for peace on the post-conflict island of Cyprus: the case of the Columba-Hypatia project

Dr Francesca Fragkoudi

Durham University. GalileoMobile

Abstract

The "Columba-Hypatia: Astronomy for Peace"" Project is a cross-disciplinary collaboration between Science Communicators (GalileoMobile) and Peace Educators (Association for Historical Dialogue and Research) in which astronomy is used as a tool for peace and diplomacy on the divided, post-conflict island of Cyprus. The project aims to inspire young people, through astronomy, to be curious about science and the cosmos, while also using astronomy as a tool for promoting meaningful communication and a Culture of Peace and Non-violence. The project brought together the various communities of Cyprus “under the same sky” to look beyond borders and inspire a sense of global citizenship, by promoting meaningful communication and interactions between its participants. To this aim, we conducted "bi-communal" educational astronomy activities in schools as well as in the United Nations-controlled "Buffer Zone" as well as astronomy nights and events for the general public. I will share the experiences and lessons learnt from using astronomy as a tool for diplomacy and for promoting peace and co-existence in a post-conflict region, such as Cyprus.

Outreach at the Pierre Auger Observatory: Agile methodology for communicating astroparticle physics with the public

Dr Beatriz Garcia[1,2], Dr. Karen Caballero[3]

[1]Universidad Tecnológica Nacional, Faculty Mendoza. [2]CONICET. [3]Universidad Autónoma de Chiapas

Abstract

The Pierre Auger Observatory has developed its activities in the field of education and dissemination of astrophysics and high-energy astroparticle physics following the iterative Agile methodology. In this sense, a permanent improvement of the tools used has been achieved. The innovations are of two kinds: externally, in terms of the offering for visitors, which are renewed approximately every five years ; but also internally, through continuous training and evaluation of the capabilities of the personnel. The link between the outreach office and the members of the Collaboration who contribute to the task is also permanent and has been reinforced. In this presentation, the improvements in the last twenty years of contact between the Observatory and the community, focusing on the new proposals will be shown. This includes the open data policy, master classes for middle-level students and teachers, the design of innovative activities that involve the community, and the presence of the Observatory in special events with the participation of students. It is worth mentioning that the evaluation of all this work and of the social impact of the Observatory allows a redesigning of strategies for improving communication with the public, taking into account social responsibility and projecting a vision for the next decade.

Commission C5 Cultural Astronomy: A new asset for Cultural Astronomy support throughout the IAU

Dr Steven Gullberg[1], Dr Alejandro Lopez[2]

[1]University of Oklahoma. [2]University of Buenos Aires

Abstract

Cultural Astronomy deals with the astronomy of past cultures, present Indigenous cultures, and as well other aspects of contemporary astronomy in culture.

Cultural Astronomy has evolved into a robust field of study that fills a distinct need for cultural understanding. The activities of the WG Astronomy in Culture have broadened far beyond what is typical for a working group considering its number of members, its association with multiple commissions, and as well the support it is providing to other organizations. Future contributions of Cultural Astronomy will now be even better accomplished by work as a regular commission of the IAU.

This new commission embraces all goals of the IAU Strategic Plan 2020-2030 and will especially be well poised to enhance efforts with Goals 4 and 5 as Cultural Astronomy is very much an attention-getter for the public and is also a fascinating way to introduce students to astronomy education.

The Commission will be the IAU's focal point for Cultural Astronomy and how it relates to other branches of astronomy, for research in the field, and for educating the public regarding examples of how astronomy is being and has been used in culture throughout world history. As such the commission will exist to support any part of the IAU desiring such assistance. The commission will build solid relationships with the OAD, OAE, OAO, and OYA.

Artificial intelligence and its role in enhancing the teaching and learning of astronomy and cosmology across the various stages of education

Prof. Abd El Fady Morcos

National Research Institute of Astronomy and Geophysics. Acadmy of Scientific Researchs and Technology

Abstract

Artificial intelligence (AI) is revolutionizing education, particularly in astronomy and cosmology, by enhancing teaching and learning experiences across different educational levels. The expected techniques in how AI technologies can personalize learning, create immersive experiences, and deepen understanding of complex astronomical concepts have been disused for different educational levels. AI capabilities like machine learning, natural language processing, and virtual reality offer interactive simulations and adaptive learning platforms to solve some of challenges in current astronomy education. It is also submitting the need for teacher training. Emphasizing ethical considerations, it highlights the importance of educators in designing AI-enabled learning environments that prioritize student well-being and academic integrity. Finally we can say that AI's potential to transform astronomy and cosmology education by inspiring curiosity, enabling deeper exploration of the universe, and nurturing scientifically literate individuals for future cosmic challenges.

Astronomy and the Ongoing Conflict in Sudan

Tamador Khalil[1], Hassan Abdalla[2,3,4]

[1]Affiliation. [2]IPARCOS and Department of EMFTEL, Universidad Complutense de Madrid, E-28040 Madrid, Spain. [3]Department of Astronomy and Meteorology, Omdurman Islamic University, Omdurman 382, Sudan. [4]Centre for Space Research, North-West University, Potchefstroom 2520, South Africa

Abstract

In this talk, I will discuss the impact of the ongoing war in Sudan on the recent development and growth of astronomy within the country. Despite the challenges posed by difficult times, we remain inspired by the enduring brightness of the stars, representing hope. Our goal is to build human skills that will serve as the foundation for re-establishing a strong astronomical research community. This community aims to make significant contributions to the global effort in understanding the cosmos.

10 years of the Pan-African School for Emerging Astronomers (PASEA)

Dr. Linda Strubbe[1], Dr. Bonaventure Okere[2,3,4], Prof. James Chibueze[5], Dr. Jielai Zhang[6,7]

[1]Strubbe Educational Consulting. [2]Centre for Basic Space Sciences, Nsukka, Nigeria. [3]National Space Research & Development Agency. [4]West African Office of Astronomy for Development - Regional Node. [5]University of South Africa, Department of Mathematical Sciences. [6]Swinburne University of Technology. [7]ARC CoE for Gravitational Wave Discovery

Abstract

The Pan-African School for Emerging Astronomers (PASEA) is a short course in astronomy for university students and teachers from across Africa, designed and taught by an international collaboration of astronomers from Africa and around the world. Founded in 2013, PASEA's vision is to build a critical mass of astronomers in Africa, and exchange teaching ideas across continents. Drawing from educational research principles, PASEA is designed to inspire students' interest in astronomy, develop their scientific practices, support their scientific identities, and offer career guidance.

The biennial school was held four times in Nigeria and Ghana. In 2022, PASEA became Pan-African, holding our first school in Southern Africa in Zambia; we also held our first online program on remote observing. PASEA 2024 will be our first school in Northern Africa, in Tunisia.

We will highlight four unique aspects of PASEA: (1) our innovative inquiry-based curriculum, in which students ask and investigate their own mini-research questions in small teams; (2) "paired-teaching," in which international partners co-teach to learn new teaching strategies; (3) our alumni community; and (4) our evaluations of student learning.

Over 10 years, PASEA has created positive educational impacts in Africa and beyond. We have almost 300 alumni from 20 African countries. Almost all continue in STEM, and 90% say PASEA was very influential for their choice of career or studies. We are thrilled that five of our alumni have returned to PASEA as instructors. We will share PASEA's accomplishments over the last decade, and plans for the decade to come.

How History Touches the Sky: Historical Instruments, Archives, and Observatories, and Why History Is Vital to Modern Astronomical Research

Dr. Sara Schechner

Harvard University

Abstract

As a science that studies distant celestial objects, astronomy deals with few things that can be touched directly. And yet, astronomy has many tangible things—scientific instruments, logbooks, and observatories, for example—which link the past to the present. There is little question about maintaining things still valuable for scientific research purposes, but why should we care about documenting and preserving the old and obsolete? One answer is that material things, when closely examined, enhance our knowledge of astronomy's history in ways that written texts alone cannot do. A second answer is that learning about the past helps us live critically in the present. Indeed, historical astronomical objects, when thoughtfully examined and analyzed, are useful to modern scientists because they offer insight into why things are the way they are, why we believe what we believe, and perhaps how we can change them.

By way of example, this talk will briefly examine some historical, tangible things that have lessons for modern astronomy. It will also highlight Commission C3's work in promoting the preservation and study of astronomy's material objects as keys to understanding the history of astronomy and astrophysics and communicating this history to the public.

Motivating school students towards astronomy through competitions

Prof. Aniket Sule

Homi Bhabha Centre for Science Education (HBCSE-TIFR), Mumbai, India. IAU OAE Center India

Abstract

IAU has adopted a multi-pronged approach to inspire school students towards astronomy. In this talk, I would like to put spotlight on one approach often overlooked by astronomy educators. Amongst student cohorts in many developing countries, astronomy themed competitions prove to be a key motivator. Competitions, by nature, are designed to reach a large number of students, something which cannot be achieved by other education efforts such as workshops and summer schools. The global competitions, if channeled in a constructive way, can motivate students to learn and research latest developments in the field, can set benchmarks for educators and kick start curricular reforms in countries where curriculum has remained static for long periods. The competitions can take many forms from art based competitions and project based competitions to problem solving competitions like Olympiads. I will discuss these competition formats through examples and propose future paths for IAU to explore in order to make further progress on its mission to bring larger sections of population in the fold of astronomy.

Diversity of knowledge on stars in indigenous communities of India and South Africa

Dr SHYLAJA B S

Jawaharlal Nehru Planetarium, Bangalore, India

Abstract

Stars have fascinated the inquisitive indigenous peoples who attempted to project their own stories to the sky. While the civilised societies recorded the heavens systematically with concepts like the coordinate system, the world views of the underprivileged are not known very well.

In a vast continent like Africa, a diverse system of nomenclature is quite apparent. The subcontinent of India (South East Asia – may be a better definition) is no exception. The most popular is the 27-star system instead of the 12-zodiac constellations, which is popular in China and South East Asia, with names of common origin and local touch, an effect of the advent of early sea-farers . Canopus is discussed in all astronomy texts for its visibility from different latitudes. There are many other stars outside the zodiac and have names based on a similar flow of thoughts. The use of stars for navigation is suggested by very simple names coined by sea farers. Pleiades has the largest variety of names and directly relates to the lifestyle of natives. It has a special place in the names of the months as well. The proverbs and stories associated with it are in use even today. Here we discuss the star names and associated celestial / terrestrial phenomena as they evolved and stayed on in the tongues of the native people. While exploring the diversity as will be narrated with many illustrative examples, we also note that the continents separated by the vast sea have some commonness in the naming of stars.

A comparative study of the prehistoric megalithic structures in India and South Africa

Dr SHYLAJA B S

Jawaharlal Nehru Planetarium, Bangalore, India

Abstract

Megalithic stone alignments and rock art structures have been reckoned as the earliest attempts to comprehend the complicated motion of the celestial bodies. Several such structures have been identified all over the globe including India, dating back to 8 to 10000BP. In spite of the man-made and natural disturbances, some structures have remained intact. The astronomical alignments of several such structures have been studied in great detail in the last couple of decades. More recent (5000BP) alignments have been identified in several excavations. The astronomical significance is verified from field work and associated solstice and equinox measurements. It is interesting that similar structures in Africa have been brought to light in recent decades. Here I propose to make a comparative study of them with those in India to arrive at common time frame of evolution of thoughts. The study is based on the field studies by British archaeologists in the last century and subsequent efforts (of Vahia et al, Menon et al, Rao et al) in India and the work initiated (by Ruggles and Wade) in South Africa. The understanding of the solar motion appears to have been achieved without any ambiguity and the attempts on lunar motion can be traced in both places. The evolution of the luni-solar calendar prevalent in Bantu communities also is probably influenced by such studies as in India. Similar studies on the rock paintings offer very astonishing results, especially in a 'double star' pattern dated to earlier than 5000BP.

The Influence of Kilimanjaro Mobile Planetarium and Telescopes on education outreach to boost Interest in Science and increase the number of Scientists in underserved regions of Tanzania.

Engineer Musa Mishamo

Kilimanjaro Planetarium

Abstract

Since its inception in 2022, the Kilimanjaro Planetarium has pioneered astronomy outreach education in Tanzania, successfully engaging over 20,000 students across diverse regions of the country. This program uses space science and astronomy concepts as catalysts to kindle students' passion for science and inspire them to pursue ambitious careers in Science. One of its distinctive features is the strategic targeting of remote regions in Tanzania, where the program conducts school visits, introducing students to stargazing and planetarium experience for the first time.

Through the innovative use of the Kilimanjaro mobile planetarium, the program creates a transformative experience for participants, offering them the sensation of voyaging through space. This immersive approach allows individuals in these remote areas to gaze upon celestial bodies such as the moon, stars, planets, and galaxies, fostering a profound interest in science. The tangible impact of the program is evident in the remarkable results and heightened enthusiasm witnessed since its inception. Notably, more than 13,000 students have expressed aspirations to pursue careers as astronauts, space engineers, astronomers, pilots, engineers, and various other scientific disciplines.

The Kilimanjaro Planetarium stands as a beacon of educational outreach, bridging the gap between underprivileged regions and the awe-inspiring realms of space science. By fostering a love for science and nurturing dreams of significant scientific careers, this initiative is contributing to the emergence of a new generation of scientists and ambitious individuals in Tanzania. The program aims to attract more youth to get into Science, Technology, and Innovation.

Title: The role of space technology for sustainable tourism development in Zululand, KwaZulu-Natal, South AfricaAuthor: Thabani Mazibuko*, PhD candidate at Durban University of Technology, South AfricaSupervisor: Professor Renitha Rampersad, Assistant Dean, Cape Peninsula University of TechnologyKeywords: *Space technology, sustainable tourism development, South Africa, Zululand Space technology and sustainable tourism.*

Mr THABANI MAZIBUKO

Group on earth observation

Abstract

Space technology has a huge potential to provide valuable support through applications and satellite communication, reliable data and accurate information for informed decision making with respect to sustainable tourism especially around fragile world heritage sites and ecotourism potential. Earth observation from space is a cost-effective way of obtaining unbiased and essential data on the physical world and will allow decision makers to use this information to understand trends, evaluate needs, and create sustainable development policies and programmes for society.

The aim of this study is to assess the contribution of space technology as a potential to provide support for sustainable tourism development in Zululand, Kwa Zulu-Natal.

A qualitative and a quantitative research paradigm adapting a mixed method approach through the use of surveys and interviews is utilised. The sample was drawn from 150 key role-players and stakeholders from the Zululand district, KwaZulu-Natal, South Africa.

Literature focuses on Global outlook, Africa and South Africa as well as local frameworks and policies in space technology and sustainable development. It engages multi-disciplinary approach to space technology approaches, with lessons learned towards interventions of space technology mechanisms for sustainable tourism development.

It will add to the body of literature on the potential of space technology through the development of an integrated model for the tourism sector that could assist Governmental agencies and private sector in developing countries to understand better and support space innovation initiatives to create the sustainable tourism sector.

Spreading the Stars! Astronomy Education and Outreach at UNIZULU Science Centre

Dr Derek Fish, Prof Aroonkumar Beesham

University of Zululand

Abstract

The University of Zululand has run an exciting Science Centre (USC) in Richards Bay, South Africa for almost 40 years, working mostly with pupils from pre-school to Grade 12, but also the general public. While not a dedicated astronomy or space science centre, USC has found these topics ideal to engage pupils and public and to introduce them to many aspects of science.

Programmes run over the past 30 years will be presented, compared and contrasted and their relative impact and effectiveness discussed. Resources for all these will be freely shared with delegates. These have included:

- a mobile planetarium (a Starlab which later became digital)
- interactive science shows which present various aspects of space
    1. Spinning in Space – on the solar system
    2. Our Spectacular Spectrum – on the spectrum and multi-wavelength astronomy as well as SKA
    3. The Wide World of Webb – on the James Webb Space Telescope
    4. In Living Colour – on light, waves and colour
    5. Astrology – comparing and contrasting astrology with astronomy
- telescope viewing evenings
- an analemmatic sundial at the USC which has also been reproduced at schools
- “Stars on Zoom” – a weekly Zoom webinar on astronomy during Covid
- “Power Planets” – a “trump” card game about the solar system
- A large, portable, outdoor scale model of the solar system

USC has presented programmes in the Centre, at Universities, in schools, public libraries, churches, on fields and on the beach at night. Valuable lessons have been learned and will be shared about effective outreach and education programmes.

Development of astronomy in Ethiopia and its future prospects

Dr Solomon Tessema

Entoto Observatory and Research Center, Space Science and Geospatial Institute. Ministry of Innovation and Technology

Abstract

Ethiopia's geographic location and astronomical legacy make it a prime candidate for astronomical observatory sites. Since 2004, astronomy in Ethiopia has expanded in terms of scientific research, human resources, infrastructural development, and linkages with other countries and continents. In this study, we provide an overview of the trajectory of astronomy development in Ethiopia, including its obstacles and future prospects at the national and international levels, as well as its impact on socio-economic development and research, education, and outreach.

Results from a recent review of 2089 astronomy education research articles from 1898 to 2022.

Dr. Saeed Salimpour[1,2], Dr. Michael Fitzgerald[3,1], Prof. Urban Eriksson[4]

[1]Deakin University. [2]IAU Office of Astronomy for Education. [3]Las Cumbres Observatory. [4]Uppsala University

Abstract

Using a mixed-methods approach to textual analysis considering 2089 publications in the field, an order of magnitude larger than the previous largest reviews of the field, this study paints a rich picture of the landscape of AER over the timespan of a century from 1898 to 2022. The 2022 cutoff was decided so that the publication record was relatively "complete" at that stage.

In this presentation, we provide a broad overview of the history of publications in Astronomy Education Research, particularly around it's modern genesis in the 1970s and it's skyrocketing growth during the 1990s. Initially this was dominated by the United States but, in recent years, this has been shifting to a situation where most recent AER research has taken place outside the USA.

We present what types of content are heavily focussed on (e.g. Celestial Motion) and areas that are fairly neglected (e.g. Galactic topics), what types of constructs are heavily focussed on (e.g. Content Knowledge) and which are not (e.g. Affective or Theoretical research).

This overview, with the publication abstracts input to an online database (istardb.org), provides a resource to researchers, educators, and other interested stakeholders allowing efficient ascertainment of previous research. This supports both researchers, allowing them to develop research questions at the cutting edge of the field, as well as practitioners, to inform their pragmatic approach based on latest research findings. We also present a set of recommendations and future outlook of the field of Astronomy Education Research.

Pearl Sky Girl Mentorship Program

Ms Mavyline Motari

University of Nairobi

Abstract

The Pearl Sky Girl is a mentorship program founded on the principles of guidance, support and inspiration to empower girls to uptake and excel in STEM disciplines. Mentors are primarily composed of accomplished women in STEM professions who can offer insights into their field and share their personal experiences and provide guidance on educational pathways and career opportunities. We facilitate hands-on activities, workshops, symposiums and discussions tailored to enhance girl's understanding and appreciation of STEM concepts with a keen interest in Physics. We seek to impart essential skills such as critical thinking, problem-solving and teamwork spirit. We intend to evaluate the effectiveness of the mentorship program using qualitative and quantitative measures. This includes the use of pre and post-program surveys, academic performance metrics, and qualitative feedback from participants on the program's impact. This mentorship program aims to break the barriers and stereotypes that hinder girls' participation in STEM fields and ensure that the girls stay through school and get to access tertiary and university education. We aspire to foster a supportive community and provide targeted guidance and resources that will empower the girls to confidently pursue and excel in STEM disciplines, thereby contributing to a more diverse and innovative future workforce.

Ancient celebrations and climate changing

Hassan Baghbani[1,2], Alireza Dosti[1], Fatemeh Jamali[3]

[1]ITAU. [2]Education service. [3]Boushehr astronomy group

Abstract

Although religion has brought together different ethnicities,
But different religions have caused the most violent and longest wars between different ethnic groups.
But the events and celebrations have always been the cause of convergence and better understanding of nations, they have built friendship and convergence. The permanence of the ancient civilization of Persia, along with the preservation of its traditions, is an example of it. The selection of four astronomical events for the great celebrations of the Persian civilization has made it long lasting.
The basis of the four Persian festivals is based on four astrological events, so these festivals are universal .
The main question: why should these four events be introduced as four global events.
Answer: To help the planet earth to solve the biggest challenge in human history (climate changes), and environmental challenges.
The festival of Tirgan (summer solstice) ,Nowruz (march equinox) Mehrgan(September equinox) Yalda(December solstice). four celebrations for planet earth , that shows how we can use sieson changing to understand the planet earth and do many helpful things for our planet. These four festivals have been so effective that the passage of several thousands years has not been able to destroy them and now they are held simultaneously in every corner of Iran and some neighboring countries.
The official registration of these four festivals and events with the cooperation of UNESCO and IAU can be a great contribution to the global convergence to solve the problem of climate change and environmental problems

STEAM in Action: NASE-UNESCO Bridges between Cultures

Dr Rosa M. Ros[1], Dr Beatriz García[2], Eng. Ricardo Moreno[3], Dr Ederlinda Viñuales[4]

[1]Polytechnical University of Catalonia. [2]National Technological University, Mendoza, Argentina. [3]Colegio Retamar, Madrid, Spain. [4]Zaragoza University, Zaragoza, Spain

Abstract

Astronomy marks our lives in diverse ways. The approach to the starry sky was important from a ritual and daily ceremonial point of view. Although we have fragments of the knowledge of the people of the past, we know that astronomy allowed us to establish patterns that became part of universal culture; intangible heritage of humanity, according to the UNESCO declaration of 2007, the starry sky connects us as human beings, establishing the link between the terrestrial and celestial landscapes, deploying a bridge that goes beyond the borders imposed on the planet. *Bridges Between Cultures* and *Seminaries N+*, are the annual proposals of the Network for Astronomy Education in Schools (NASE) associated with the UNESCO call for May 16 – IDL. These activities aim, hand in hand with universal astronomical themes, discoveries of the modern era and great challenges of science dedicated to the study of the "light" that comes from the cosmos, to reestablish the links that identify us as a species.

In this presentation we will show the topics addressed from the beginning of the proposal, which covers challenging topics in Astronomy, Astrophysics, Astrobiology and Astroculture. The indicators that allow us to evaluate the impact of the carry out these activities and plan new ones, the testimonies of participants who constitute diverse audiences who risk developing astronomical topics in the classroom and beyond it, in many cases for the first time, will be presented in order to show the power of the discipline in the public communication of science.

Astronomy in a National Marine Park in Iran as a Model for Using Astronomy for Sustainable Development

Hassan Baghbani[1], Mohammad reza Fooladi[2], Sahar Sahhafizade[2]

[1]ITAU. [2]Nakhilo sustainable development school

Abstract

The Iranian Teachers Astronomy ' Union has been making efforts for over twenty years to play a significant role in environmental protection and sustainable development by educating teachers and the local community through the allure of celestial knowledge. This model, as a successful one, can be utilized in other countries as well. An example being the comprehensive management of the Nakhiloo Marine National Park in the northeastern part of the Persian Gulf. Previously, one of the major sources of income for the local people in this area was logging, illegal hunting, smuggling, and out-of-season fishing, The efforts of environmental protection organizations in this area didn't be successful . Therefore, the only way to protect this area was local community activities.

ITAU , by using on past experiences, initially gained credibility among the local community by organizing astronomy workshops for teachers and students. Subsequently, by establishing a Sustainable Development School in suitable part of the national park, they focused on educating and empowering the local community and on the other side, by combining the natural attractions with the dark skies and involving the local community, they built a large astronomical complex comprising an observatory, planetarium, conference hall, accommodation facilities, and a restaurant. Thousands of tourists visit this complex annually, and their numbers are increasing each year. Other valuable educational activities have also been carried out, such as teaching watershed management and proper planting of native trees, which have played a vital role in land sustainability

Using Zooniverse to Enhance Classroom and Group Engagement with a Suite of New Educational Tools

Lindsay House[1], Laura Trouille[2,3], Cliff Johnson[2,4,3], Samantha Blickhan[2,3], Chris Lintott[5,3], Lucy Fortson[6,3]

[1]University of Texas at Austin. [2]Adler Planetarium. [3]Zooniverse. [4]Northwestern University. [5]Oxford University. [6]University of Minnesota

Abstract

Zooniverse has launched over 450 participatory research projects engaging over 2.7 million registered participants. The projects cover a diverse range of disciplines, from astronomy to cancer research to zoology. Zooniverse has become essential in the researcher's toolkit. And by engaging the public meaningfully in scientific research, Zooniverse advances the IAU's mission of impact and accessibility through fostering community growth and global collaboration while providing inclusive, family-friendly public engagement.

In addition to individual participants classifying on projects and engaging in the discussion forums, Zooniverse is used by thousands of groups in formal and informal learning settings such as schools, museums, and libraries. Classroom.zooniverse.org provides resources and support for these efforts. However, a common request has been better tools to track group-based collaborative effort on the platform. In response, in 2024 Zooniverse released a suite of new features to share individual and collective impact. Whether it's for an after-school club, corporate volunteering program, or a friend/family group, these new features provide new avenues for fostering community and collaboration. For example, educators can use these new tools to tailor classification challenges (and rewards) for their students, further motivating and integrating participatory science experiences into their curriculum. In this Talk we share pathways and lessons learned from leveraging participant data to celebrate impact and further motivate engagement. And we welcome feedback and collaborations to refine these features so that they are most useful to our diverse audiences.

PLOAD special days and its non-formal education activities in virtual mode

Joana Latas[1,2], Patrícia Figueiró Spinelli[3], Joana Marques[4], Joana Silva[1], Rosa Doran[1]

[1]NUCLIO. [2]Center for Research in Education and Psychology of the University of Évora (CIEP-UE), Portugal. [3]Museum of Astronomy and Related Sciences, Brazil. [4]Institute of Astrophysics and Space Sciences (IA), University of Coimbra, Portugal

Abstract

Portuguese Language Office of Astronomy for Development (PLOAD) promotes the use of astronomy as a tool for development in Portuguese-speaking countries and communities, supporting the strategic plan of the International Astronomical Union (IAU). PLOAD aims to promote scientific literacy through accessible resources for all Portuguese-speaking countries and to contribute to their active participation in the field of Astronomy and Space Sciences. This is achieved by providing access to cutting-edge resources, establishing partnerships with the educational community, and highlighting the cultural importance of sky observation in the language and history of these countries. The diversity within the PLOAD network presents unique challenges and opportunities for scientific, technological, and educational development. Moreover, being represented on four continents, PLOAD faces additional geographical challenges. To overcome these challenges, digital communication is being a central tool in our actions, allowing PLOAD to achieve greater community engagement in the activities, bridging the gap between science and society.

This poster focuses on the non-formal education activities virtually and promoted in three Special Days related with PLOAD's mission: World Science Day for Peace and Development (November 10), International Day of Women and Girls in Science (February 11), and World Portuguese Language Day (May 5). During these celebrations, a joint program with a global online component and a local face-to-face one was organized, which will be presented. These diverse activities allowed participants, mainly young people, to share the Portuguese language and science curiosity through meaningful interactions.

The Impact of the International Astronomical Union in Bolivia, through the work of the National Coordination of Diffusion and Education office since 2019.

Natieonal Outreach Coordinator Paola Daniela Ochoa Paniagua.

National Outreach Coordinator Bolivia - IUA. CEO - ANDRÓMEDA Company.

Abstract

In 2019, the year of celebration of the 100 years of the IAU, Bolivia has its first NOC, with this the IAU begins to gain popularity in the national territory. The IAU's Global activities are carried out for the first time with the support of amateur groups of professors and professionals in astronomy.
The diffusion office, acquired a first-hand role, was established independent of any other institution, which gives it the advantage of carrying out activities without highlighting the local institution, but rather the IAU itself with its global activities.
We named the first exoworld for Bolivia, we held national astronomy meetings and astronomical camps, “Telescopes for All” campaigns, “100 Hours of Astronomy”, “World Lunar Observation Day” “Girls and women in Science” workshops for teachers, students and amateur people, etcc. From these activities, astronomical communities grew more both in urban and rural areas.
All these activities are the result of the work of associations, clubs, professional and amateur teachers, who, motivated by the presence of the IAU, made it possible. Without a doubt, having the support of the IAU has been highly positive for our country and we continue working so that the institution has more presence in our country.

Astronomy Day in Schools: Commonality and diversity of cultural astronomy and collaboration of research projects

Dr. Akihiko Tomita

Wakayama University

Abstract

The Astronomy Day in Schools project organizes the online program on the occasion of equinoxes and solstices. Students and teachers from various countries introduce each other not only their astronomy activities, but also their local cultural events and traditions and their relevance to astronomy. In the astronomy activities, the students have started the night sky photography project to raise awareness of light pollution issue. Cultural events and traditions are diverse from region to region, but at the same time very similar in some aspects. One reason for this may be that the yearly cycle of the landscape and people is related to the yearly cycle of the heavens, and another is the commonality in the way people react to the cycle. There are also presentations on ancient architectures and examples of how astronomy was incorporated into daily life at that time. As school materials, apart from the direction of developing advanced astronomy and STEM contents, applications to geography, history, art, music, and moral classes are examples of cross-disciplinary materials related to astronomy which are appealing to teachers and students who are not necessarily so astronomy-oriented. The teachers sometimes learn about local traditions only after hearing the students' presentations. In this talk, I will introduce some of the above examples in previous programs and feedback from teachers and students. The continents of the participating countries are so far mostly Eurasia and Latin America, and we would like to expand to other areas in the future.

ASTRONOMY EDUCATION IN TANZANIA

Mr. George Kato

Afrikagera Geological Center

Abstract

Astronomy activities in Tanzania are at a minimum level, despite the potential advantages space science comes with in our societies. Research and education in space is vital for various sectors like agriculture, transportation, health, mining, geology technology and many others. Having a satellite in space means getting well prepared for the heavy rains, discovering potential mineral resources, building resilience to geohazards and exploring the universe. It is with this that astronomy education is important in several levels of education for the development of the people and the Nation. This presentation examines existing curriculum structures, educational resources and the level of integration of astronomy in schools. It also highlights initiatives that promote astronomy awareness among students and communities at large.

Designing urban elements and the identity of cities with an astronomical approach

Mr Hossein Khezri[1,2], Ms Maryam Papari[3,1]

[1]Associate of Commission C1 WG Astronomy Education Research & Methods. [2]Associate of Inter-Commission C1-C2-C3-C4 WG Astronomy in Culture (WGAC). [3]Director of Mehr observatory (Iran)

Abstract

The presence of elemental elements in addition to beauty improves the quality of space, and this quality affects the human mind

and affects the sense of place and collective memories of citizens. Urban planners should use urban elements that promote the

transfer of urban identity to the city, which helps citizens to be satisfied and improve the quality of urban environments. Urban

elements play an important role in fostering urban identity and empowering citizens, and should be designed in such a way that

their readability is consistent with the events and events of the citizens and their plans are coordinated.

By strengthening citizen science, especially astronomy, people's view of their surroundings will change and in the long run it can have a significant impact on the development of astronomy in other societies.

These symbols include astronomical elements, solar calendars and sundials, etc.

Ethiopian Amateur Astronomy Community at the Ethiopian Space Science Society: Achievements, Challenges, and Future Prospects

Kirubel Menberu Alemu

Ethiopian Space Science Society (ESSS). Space Science and Geospatial Institute (SSGI). Office for Astronomy Outreach (OAO)

Abstract

The Ethiopian Space Science Society (ESSS) serves as a hub for astronomy enthusiasts, nurturing a vibrant community dedicated to science communication. One of the key initiative of ESSS is the development of an amateur astronomy community with access to telescopes and maintenance capabilities. This presentation showcases the achievements, challenges, and prospects of the Ethiopian Amateur Astronomy Community at ESSS.

ESSS has significantly contributed to promoting astronomy awareness and education across Ethiopia. Through outreach programs like public lectures, school visits, and stargazing events, the community has engaged a diverse audience, igniting a passion for astronomy among students, teachers, and the public. The community's interest in stargazing has also expanded to include astrophotography and live streaming of astronomical events.

Despite successes, the community faces challenges such as limited resources and infrastructure, hampering outreach efforts. Purchasing telescopes in Ethiopia is challenging due to the lack of vendors and cumbersome customs procedures. ESSS has resorted to DIY maintenance for telescopes and accessories due to these challenges. However, the growing interest in astro-tourism could lead to policy changes to improve access.

Looking ahead, the Ethiopian Amateur Astronomy Community at ESSS aims to overcome these challenges and expand its impact by including telescope training, technical support for telescope owners, and furthermore enhancing collaboration with international partners, and advocating for increased support for amateur astronomy in Ethiopia.

This presentation provides a comprehensive overview of the Ethiopian Amateur Astronomy Community's journey at ESSS, highlighting achievements, challenges, and future aspirations in advancing astronomy education and outreach in Ethiopia.

Gender Sterotypes and Difficulty in Promoting Girl-Child Education in Nigeria: The way out

Chioma Okany, Timothy Egbuim, Francis Obieti, Evelyn Sam-Ngwu, Dr Chukwujekwu Ofodum, Dr Bonventure Okere

NASRDA-Centre for Basic Space Science ans Astronomy, Nsukka

Abstract

One area that seems to have not been well explored by researchers is the issue of gender sterotypes and girl-child education improvement in STEM, especially in Astronomy Education in Nigeria.

According to the United Nations (SDGs) 5, gender equality is the bedrock of an inclusive society. Girl-child participation in Astronomy education in Nigeria has been limited due to political, societal, and religious beliefs. Truly, this sterotype is a cankerworm that needs complete eradication in our society. Due to the broad ethnic and religious diversity, most cultures and religions frown at girl-child active participation in Astronomy/STEM activities. In some regions of Nigeria, tradition entails that the girl-child is relegated to house chores and child-bearing. A quantitative survey on willingness and possibility of activating Astronomy inclusion in Nigeria revealed that most girls shy away from participation in Astronomy/STEM-related activities. Incidentally, these problems were attributed mainly to religion and ethnicity. The Astro_girl child project aimed to encourage girl-child education in STEM/Astronomy-related courses in Nigeria. Inspite of all these efforts aimed at improving STEM education since 1859, the benefits of scientific and technological development have been unevenly distributed gender-wise. In other words, girl-child participation in Astronomy and STEM-related activities cannot be compared in any way with that of their male counterpart in this modern age. In light of the above, there is a need for active sensitization among boys, girls, and parents in all parts of Nigeria, for the effective realization of UN SDG-5 in Nigeria using education as a tool.

Advancing STEM Education and Community Engagement: The Giant Magellan Telescope Approach

Valerie Hirschberg

Giant Magellan Telescope

Abstract

This oral presentation will provide a comprehensive overview of the Giant Magellan Telescope's approach to the design, development, and implementation of its education, public outreach, and community engagement programs all guided by our mission to foster interest, literacy, diverse participation and sustainability in STEM fields. We will explore our methodology, current initiatives, outcomes, key learnings for the astronomy community, and future directions.

Our commitment to education, outreach and engagement is deeply rooted in the conviction that collaboration and partnership are catalysts for change. Recognizing that advancing STEM interest, literacy, and participation requires a collective effort, we actively seek collaborations with experts and community stakeholders. This approach ensures the active involvement of our intended audiences and communities, with a profound emphasis on prioritizing community voices and needs. The presentation commences with an overview of our existing programs, their tangible impact, and lessons learned. We will provide the profession and community key insights into our approach and processes to developing initiatives that are rooted in a community-astronomy model. Finally, we'll provide a glimpse into our future education, outreach and community engagement endeavors and strategic directions.

A new approach to teach astronomy

Prof. Sun Kwok

University of British Columbia. University of Hong Kong

Abstract

In our education system, science is often presented to our students as a series of facts. In fact, science is about the process of rational thinking and creativity. What we consider to be the truth is constantly evolving and has certainly changed greatly over the history of humankind. The essence of science is not so much about the current view of our world, but how we changed from one set of views to another. In a course designed for the Common Core program of the University of Hong Kong, I use the historical development of astronomy to illustrate the process of rational reasoning and its effect on philosophy, religion, and society. I begin with a description of basic observations, summarize the patterns observed and the problems they pose, and discuss the suggested theories and their implications. The pros and cons of these theories are evaluated alongside alternate theories. This approach differs from typical science textbooks, which usually take an axiomatic approach by first stating the correct theory and deriving the deductions before comparing them with experimental results. With this historical approach, students can better understand the scientific process and learn from this process when they tackle real-life problems in their careers.

Bringing Astronomer to Empowering Astronomy Club at Secondary School: Experience in Malaysia

Dr Raihana Abdul Wahab

University of Malaya

Abstract

The Astronomy Club at Secondary School plays a very important role for nurturing student's curiosity about astronomical sciences and fostering their scientific inquiry through the theoretical knowledge and practical applications. However, due to factors like a lack of experience and a deviation from complete, organised theoretical and practical training that can be translated into student-led hands-on activities, these club members are unable to fulfil this role. Hence, the goal of this project is to strengthen the function of the secondary school astronomy club by combining theoretical and practical instruction under the supervision and direction of qualified astronomers. As a result, this project creates a simple module in Malay Language named "Modul Celik Falak" that serves as curriculum direction for an astronomy club. Consequently, this project is being carried out to allow members of the astronomy club to share their knowledge with other students and the local community. This project was warmly received by both the teachers and the students who attended the training. The response clearly demonstrates that the majority of club members believe the astronomy club has a positive impact on capturing students' curiosity, encouraging lifelong learning, and developing the next wave of astronomers and the universe enthusiasts.

KNOWLEDGE AND PERCEPTION OF ASTRONOMICAL EVENTS AMONG STUDENTS OF HASSAN USMAN KATSINA POLYTECHNIC, KATSINA KATSINA STATE, NORTHERN NIGERIA

Mr. Suleiman Iguda Ladan

Hassan Usman Katsina Polytechnic, Katsina Katsina State, Nigeria

Abstract

ABSTRACT

Over the years astronomical events such as lunar eclipse, solar eclipse and the falling of meteorites etc have been occurring in different parts of the world and how such events are viewed depend largely on the knowledge and perception among the citizens. This paper examines knowledge and perception of astronomical events with particular reference to the Friday 27th July 2018 lunar eclipse, among students of Hassan Usman Katsina Polytechnic, Katsina Katsina State. The sampling of a Polytechnic for the study is apt as the Polytechnics are science and technology based institutions that play a critical role in the technological advancement of the country. Data for the research were generated using structured questionnaire survey conducted on two sets of students studying National Diploma Science Laboratory Technology and National Diploma Mass Communication numbering one hundred (100).The results have shown a varying degrees of knowledge of the lunar eclipse as the Mass Communication students depict an average while the Science Laboratory Technology students depict above average knowledge. In terms of the perception of the event only a small percentage of the students perceive the event as a normal astronomical event that occurs from time to time. It is therefore recommended that efforts should be made towards improving the student's knowledge of astronomical events and right perception of the event as experienced in Nigeria.

Key words: Knowledge, perception, astronomical events, students, Katsina.

From Analog Roots to Digital Frontiers: Investigating the Modern Planetarium in Astronomy Education

Dr Alexander Sivitilli[1,2], Prof Saalih Allie[1]

[1]University of Cape Town. [2]Inter-University Institute for Data Intensive Astronomy

Abstract

The modern planetarium, blending digital immersion with its traditional analog roots, still serves as an important educational tool in astronomy. This study investigated the role of the digital planetarium in teaching and learning through two main inquiries: a) examining student engagement with the digital planetarium, and b) identifying factors influencing the teaching and learning space within the planetarium. Data for these inquiries were derived from both student responses and observational data, analyzed using the Grounded Theory Method. Responses were collected from university students during two visits to a digital planetarium, integrated into their introductory astronomy course. An instrument was created to assess their overall experiences and educational content engagement. Analysis of individual student responses revealed key ideas grouped into categories, forming a localized mid-level model of student engagement. The concept of a "spectrum of attentiveness" emerged, influencing student engagement levels, along with an optimal level for relevant engagement affected by coincident distractions. Detailed observations, gathered during multiple visits to the planetarium, also contributed to constructing categories for a second localized mid-level model. This model outlined key contextual factors shaping the planetarium's teaching and learning space. To expand on the initial inquiries, these two localized models were integrated with broader cognitive theory, specifically Working Memory (WM) and Cognitive Load Theory (CLT). The synthesis of these models culminated in the development of a comprehensive Model for Curriculum Design in the Planetarium (MCDiP), aimed at systematically enhancing the digital planetarium as an effective teaching and learning space.

Micrometeorites Project in Iran, Inspiring Discovery and Learning Journey

Seyedeh Fatemeh Hasheminasab[1], Hosan Fadaei Yekata Kaldehi[1], Rahimeh Foroughi[2]

[1]Thaqeb Astronomical Association. [2]Znjan University

Abstract

This is a scientific report about the international Micrometeorites project based on NASE's proposal for the International Day of Light, which was held in Iran by the Thaqib Astronomical Association.

It would describe our experience coordinating and conducting a special program on micrometeorites in Iran. At the end of this project, 212 students and 38 teachers from nine provinces in Iran actively participated. Our aim was to make space exploration captivating and accessible for Iranian students. The micrometeorite project empowered teachers across the country to bring the wonders of the universe into their classrooms. Students not only observed the night sky but also had the tangible experience of handling actual pieces of space debris, enriching their understanding of astronomy.

Hack4dev Data Science Hackathons

Dr Nikhita Madhanpall[1,2], Mr Eslam Hussein[3]

[1]Wits Centre for Astrophysics. [2]Development in Africa with Radio Astronomy (DARA). [3]Inter-University Institute for Data Intensive Astronomy (IDIA)

Abstract

Since 2018, Data Science Hackathons have been conducted in collaboration with DARA Big Data, a sister project to DARA (Development in Africa with Radio Astronomy), the Inter-University Institute for Data Intensive Astronomy (IDIA), and the Office of Astronomy for Development (OAD). The primary goal is to enhance data science capacity across the eight SKA African partner countries forming the African VLBI Network (AVN).

Between 2020 and 2023, the programme hosted 3-4 hackathons annually, featuring virtual events accessible to participants across Africa and benefiting around 300 individuals from 14 countries. These hackathons provided hands-on exposure to data science and machine learning, engaging a diverse participant pool, including undergraduates, postgraduates, and young professionals in STEM fields. This active involvement in real-world projects instilled confidence for future pursuits in industry or research. Each 3-day event comprised training and ideation segments, where participants delved into data science concepts using Jupyter Notebooks within IDIA's ilifu cloud computing system.

In 2022, the initiative evolved into the Hack4dev project led by IDIA in collaboration with the OAD, African Astronomical Society (AfAS), and BRICS Astronomy. The Hack4dev Data Science Hackathon programme now follows a new framework for sustainability and scalability. This involves an annual global call for individuals or groups interested in organising hackathons. Selected organisers undergo comprehensive in-person training to execute successful 2-3 day Data Science Hackathons in their respective countries. Additionally, hackathon projects, based on current research, offer participants the opportunity to generate new solutions with the potential for publication.

Embracing the Night Sky: Astro-Tourism Potential in Botswana

Mr Onkabetse Sengate

Botswana International University of Science and Technology. University of Kwazulu-Natal

Abstract

Botswana, with its vast expanses of pristine wilderness and remarkably low light pollution levels, presents a unique opportunity for astro-tourism enthusiasts to explore the wonders of the cosmos. This poster highlights the potential and challenges of astro-tourism in Botswana, offering insights into the socio-economic and environmental impacts of this emerging niche within the country's tourism sector. By examining the factors driving the growth of astro-tourism in Botswana and the strategies for sustainable development, this presentation aims to shed light on how Botswana can leverage its celestial assets to promote economic growth, cultural exchange, and scientific discovery while preserving its natural heritage. Join us as we journey through Botswana's enchanting night sky and discover the limitless possibilities of astro-tourism in this captivating poster presentation.

Perspectives on Decolonising Astronomy Towards An Inclusive Environment

Assistant Professor / Director of Communications Thilina Heenatigala

Earth-Life Science Institute (ELSI)

Abstract

A form of colonisation exists in scientific academia, education and outreach. It is identified through the imbalance of power and wealth between academia in developed and developing countries, Global North and Global South, and Western to East. Also recognised as 'parachute science' wherein experts from formerly mentioned regions would go into under-developed or Global Southern areas for one-off activities without collaboration with local expertise or long-term plans. The issue of 'colonial science' is reflected in astronomy research, development, education and outreach. These colonial structures continue to shape astronomy efforts, which could work against the development of underdeveloped communities. As a community of astronomy experts, it is essential to consider how resources such as expertise, guidance, and materials are shared among the communities. And collaborations that go hand-in-hand with local experts and address local needs. This talk will address the growing concern of 'parachute science' or 'colonial science' in astronomy and move towards an inclusive environment.

Office of Astronomy for Development. Flagship 2: Astronomy for Mental Health Overview

Mr Dominic Vertue, Dr Joyful Mdhluli, Mrs Mampho Ledimo

OAD

Abstract

The Office of Astronomy for Development's flagship program, Astronomy for Mental Health, harnesses the power of astronomy and the night sky to improve mental health and well-being.

I will share the work of the Office of Astronomy for Development (OAD) in integrating astronomy and mental health. Our work builds on research that shows engaging with astronomy can inspire awe, spark curiosity, and relieve anxiety and depression.

In this presentation, I will discuss the origins of this program, including supporting literature on astronomy's benefits for mental health. I will outline the challenges we faced in bringing psychology and astronomy together and the barriers that still need to be overcome to firmly establish astronomy as a mental health support tool, sharing lessons learned and best practices from our mental health astronomy initiatives along the way.

Can James Webb Telescope discoveries inspire the next Albert Einstein to come?- How to make Astronomy Accessible to the AfricanYouth?

Ms Basia Nasiorowska

AfAS

Abstract

This paper discusses and explores the idea of promoting Astronomy to the youth of Africa in conjunction with the James Web Telescope discoveries.

The JWST's new images are beautiful and at the same time scientifically valuable. Currently they are known only to a selected group of scientists, astronomers, amateur astronomers and all other knowledgeable enthusiast. How can an African youth be exposed to and then inspired by the JWST imagery and become a journalist, astronomer, astrophysicist or an Astronaut?

The surrounding cosmos has captured the imaginations of generations and is inspiring technological innovations and artistic expressions. JWST showcasing galaxies across the universe and other cosmic imagery can inspire the youth of Africa as long as it is made known and accessible.

Observatories such as Meer KAT radio telescope in South Africa would be a good starting point to be an introduction to the projects to better understand how galaxies are born and exist by observing the stars.

The interest can be born from star gazing initiatives by communities outreach projects through to

competitions such as **"From Star Gazing through the Galaxies to Living on Mars and Moon Competition".** Participants can express the beauty of Space as imaginative works of art such as paintings, drawings or digital forms inspired by JWST.

Competitions can be the engine to drive entrepreneurial spirit and form future African startups in Astronomy and Space Technologies.

The African youth is motivated and excited to be part of the discoveries and experience the fruits of such amazing tools as James Web Telescope.

GLOBAL ONLINE TEACHING AND RESEARCH TRAINING IN ATOMIC ASTROPHYSICS

Prof Sultana Nahar

The Ohio State University

Abstract

With realization of globalization of knowledge can bring scientific advances faster, one important objective in all areas of STEM has been globalize education and research. I found that objective was served most efficiently by teaching and training research online through zoom platform during COVID-19 pandemic. I have been delivering the 3-weeks long research training course "Atomic Astrophysics and Spectroscopy with Computational Workshops on R-matrix and SUPERSTRUCTURE codes" in-person internationally since 2013. It took a pause due to COVID-19. However, guiding students and researchers on the zoom in 2019, I realized the potential of zoom and transformed my course for virtual presentation, and offered it successfully to 75 participants organized by Choaib Doukkali University of Morocco in 2020. The following year, I expanded it to over 100 participants from 11 countries, from USA, Africa, Middle East to Asia, joining at the same time, afternoon in Mexico to early morning in Bangladesh. Interestingly and fortunately, the participants were enthusiastic with the subject materials with no complain on the time zones. The staff of my partner Ohio Supercomputer Center for facilitating high performance computers for the computational workshops provided all technical help patiently to the non-English speaking participants. The other best part was forming a what's app group of the participants who would help each other with projects and running programs, and ended in forming a wonderful bond among them. A news article of it was published on the front page of American Physical Society Newsletter Vol 31, No. 6, page 1 (2022).

Astronomy Outreach and Education in Ugandan Secondary Schools

Dr Cosmos Dumba[1,2], Dr Benard Nsamba[3,4]

[1]Mbarara University of Science & Technology, Uganda. [2]Thuringa Landessternwarte, Tautenburg, Germany. [3]Max Planck Institute for Astrophysics, Garching. [4]Mbarara University of Science & Technology

Abstract

Astronomy education in Uganda is on the rise as more public universities have included Astronomy in their curricula. This has lead to an increase in the necessity of Astronomy awareness in Secondary schools, which feed the universities with science students, and to the general public. To this end, we embark on a nationwide program, visiting secondary schools (high schools), conducting Astronomy outreach activities. These activities are designed to fit with the newly designed secondary school curriculum that is learner centered.

We report the outcome from the outreach visits to secondary schools from the East, North, West, South West and Central regions of Uganda. We also show that such programs highly motivate the learners to take on Science and Engineering based higher education courses. It is however noted too that in regions that are further away from the cities, the knowledge on Astronomy is still low and therefore more awareness has to be done to widen the scope.

Practice of Stargazing Tour on a Ship as a Astro-Tourism

Dr. Shio Kawagoe[1], Dr. Nobuhiko Kusakabe[2,3]

[1]The University of Tokyo. [2]Astrobiology Center, NINS. [3]National Astronomical Observatory of Japan

Abstract

Recently, astro-tourism, in which people leave residences to look up at beautiful starry skies, has attracted people. The main sites chosen as fields for astro-tourism research are those with international observatories and those accredited by the International Dark Sky Association (IDA). Astro-tourism is becoming popular in Japan. However, there is a paucity of academic research on astro-tourism.

This study implemented a tour to observe the Geminids meteor shower on a ferry as a case study of astro-tourism in Japan. In this tour, the participants boarded the Tokyo-Kyushu Ferry instead of observing at a specific location as certified by IDA. They observed from the ferry's deck as it traveled over the Pacific Ocean. Before observing, the author lectured on the Geminids meteor shower. After the lecture, we surveyed 27 tour participants.

It rained on the tour day in December 2023, and the Geminids meteor shower could not be observed. However, about 80% of the participants answered "very good" or "good." About 90% of the respondents said they would like to participate in future tours with astronomy as a theme. The results also suggest that tours with astronomy as a theme have the potential to attract a wide range of participants, regardless of their background in the humanities or sciences.

Investigating learners' experiences and attitudes towards astronomy in the New curriculum of Uganda: A case study of Kabale Municipality

Dr Isaac Habumugisha

Kabale University, Department of Physics

Abstract

Astronomy as natural science, is magnificently rich in concept. It is embedded in the various fields of modern 21st century; Science, Technology, Engineering and Mathematics (STEM). Slightly before the onset of Covid-19 pandemic (February 2020) in Uganda, the government rolled out the new lower secondary education curriculum (LSC). The aim of LSC was to equip learners with an enhancement skills training as opposed to the old curriculum, which was designed on colonial system. Interestingly, concepts on astronomy for beginners were included in the New LSC, but do learners have any experience in the content and how interested are they towards it. That is why this study investigated the learners' experience and attitudes towards Astronomy concepts. A total of 160 students from six secondary schools in Kabale Municipality (St. Marys' College-Rushoroza, Ndorwa Secondary School, Trinity College, Kabale Brainstorm High School, Rock High School, and Kigezi College-Butobere) were randomly sampled. A questionnaire-with carefully chosen set of questions was administered. Majority of the learners (67%) were found to have heard basic knowledge on astronomy, with 33% not conversant with astronomical concepts when first introduced in class. 81% of them were highly interested in Astronomy. Additionally, learners stated that they heard about astronomy from various sources like T.V programs, YouTube videos, among others. However, majority of the teachers were not trained about astronomy concepts. Thus thorough facilitation in teaching of Astronomy and Astrophysics is required. It is recommended that Physics teachers be given refresher courses and the scope of astronomy and astrophysics expanded.

Awareness, Interest and Challenges of Studying Astronomy among Students in Nigerian Universities

Dr Emmanuel Eseyin

Nigerian Institute of Social and Economic Research

Abstract

Never in the history of Africa has there been the need to better understand the way forward out of the social, cultural, economic and political crises bedeviling the continent than now and Nigeria is not excluded. Deep interest in astronomy can serve as a way out of this quagmire but this interest can only begin from attracting the interest of students who eventually become astronomers. This study hence focused on assessing the level of awareness, interest and challenges of students in embracing astronomy in Nigerian Universities. The survey sampled respondents from first generation Nigerian Universities. The Universities selected are University of Ibadan in the South and Ahmadu Bello University in the North. Purposive sampling technique was used to select 104 astronomy students in their first and final year in these Universities. These respondents responded to a structured questionnaire which was analyzed using descriptive statistics. The result of the study indicated that the level of awareness and interest of students in astronomy is low in the Universities. Some of the students offering the course had no option after failing to get their first choice courses. The challenges in embracing astronomy included parental career influence, low career prospects and the absence of human and material resources for the programmes in Nigerian Universities. It was recommended that increased funding and political will need to be channeled to this area for Nigeria's socio-economic stability

Astronomy as a conflict zone

Dr. Alejandro M. López

Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET). Instituto de Ciencias Antropológicas, Universidad de Buenos Aires

Abstract

The title of one of the axes of the Division C Days is "Astronomy in conflict zones." This expression could be understood as a reflection on how the work of academic astronomers residing in conflict zones is carried out and can be sustained. Also the expression could be linked to a reflection on the role that astronomy can play in reducing tensions and conflicts in a troubled world.

In this work I maintain that another, an essential, sense of the expression is a critical analysis of how the practice of professional astronomy has contributed to the generation of different conflicts. To do this I will use a cultural astronomy perspective, analyzing cases coming from my experience of 25 years of ethnographic fieldwork on the astronomy of indigenous peoples, and from my experience as chair of the WG on "Astronomical Heritage in Danger", and as part of the Joint Committee on Culturally Sensitive Sites (CSS) –of the IAU, RAS, AAS, ISAAC, and SIAC–. I will analyze these cases not as isolated situations, but looking at the panorama as a whole and seeking to understand its structural characteristics. To do this, I put them within its broader social framework, with the aid of social sciences. I will also critically study some of the strategies deployed in recent times to try to overcome these tensions. Finally, I will propose possible lines of action to address these problems in our individual and collective professional practice.

The development of Astronomy in Botswana through Outreach

Dr Kushatha Ntwaetsile

Botswana International University of science and technology

Abstract

Astronomy as a field in Botswana is still in its infancy and developing interests in Astronomy is crucial for the development of Astronomy. Schools outreach can be used to increase the interest of the teachers and students in Astronomy and also enhance the interest of young people in appreciating and studying Astronomy-related courses at University. Outreach is an important tool for reaffirming the critical importance of science. This presentation will center on previous and ongoing outreach initiatives designed to involve the students in astronomical exploration. In the last eight months, the Botswana team, in collaboration with the Botswana International University of Science and Technology, has organized diverse astronomy outreach events, encompassing teacher training, school visits, stargazing sessions, and more.

SPACE OUTREACH PROGRAMS IN KENYAN UNIVERSITIES.

Mr. Kimani Nyoike[1], Mr. Samuel Nyangi[1,2], Ms. Olyvia Gatwiri[3]

[1]Leo Sky Africa. [2]University of Nairobi. [3]Kenyatta University

Abstract

Over the past year, Leo Sky Africa has engaged in extensive outreach initiatives with Kenyan universities, particularly through collaborations with the University of Nairobi and Kenyatta University. Our efforts have included organizing Astro-nights and workshops at the University of Nairobi, covering diverse topics ranging from computer science to black holes, alongside sessions dedicated to highlighting the role of women in astronomy. Complementing these educational endeavours were public star-gazing events and captivating planetarium shows. Additionally, our partnership with Kenyatta University facilitated practical workshops focusing on drones and satellite technology, providing students with invaluable industry exposure. During World Space Week 2023, we further expanded our reach by joining forces with the Kenya Space Agency, Technical University of Kenya, Jomo Kenyatta University of Agriculture and Technology and Kenyatta University to address the four thematic areas of Astronomy and space science, earth observation, space and satellite technology, and space systems engineering. Through these collaborative efforts, we have strived to foster a deeper appreciation for space exploration and technological innovation within the Kenyan academic community. In this presentation, we present the work done in a bid to continuously build capacity and a community around space science education in Kenyan Universities, while creating a platform for students to engage with the ever-growing space industry.

The Astronomy Education Journal: A vehicle for publishing your practice and research

Professor Urban Eriksson[1], Dr. Saeed Salimpour[2]

[1]Dept. of Physics and Astronomy, Uppsala University, Uppsala, Sweden. [2]Deakin University, Melbourne, Australia

Abstract

In 2019, following the inaugural AstroEdu Conference in 2019, Garching, at the ESO Supernova, the international Astronomy Education Journal (AEJ, astroedjournal.org) was founded by Prof. Urban Eriksson and the late Prof. Paulo S. Bretones.

AEJ aims to meet the needs of the astronomy education community by providing a location for all manner of practical, newsworthy and scholarly publications involving developments in the field. In a sense, the journal tries to capture the original spirit whilst taking on board the important lessons from the, now out-of-print, Astronomy Education Review. By focusing on building community collaboration, disseminating important news and opinions, while also maintaining a section on formal, technical, Astronomy Education Research (AER). This research section intends to offer to you a compliment to the current scholarly discipline-based work undertaken by Latin-American Journal of Astronomy Education (RELEA), the Journal of Astronomy & Earth Sciences Education (JAESE) and, recently, the acceptance of AER articles into Physical Review Physics Education Research (PRPER).

There are also a less formal, peer-reviewed, but edited and curated section that contains other relevant material, such as, news, resources, correspondences, classroom and astronomical activities, to help circulate information among the community.

In this talk I will present the successful journey of the journal from its inauguration till today, where three volumes with very excellent articles has been published out of the many manuscripts that has been submitted to the journal. I will describe the width and breadth of articles and also discuss AEJ future directions.

Introductory Astronomy students' reasoning about astrophysical phenomena within their observational experience

Mr Chad Leukes, Professor Saalih Allie, Associate Professor Dale Taylor, Associate Professor Sarah Blyth

University of Cape Town

Abstract

The present contribution forms a broader programme of research aimed at understanding how students reason when engaging with astronomy concepts. To this end an instrument consisting of 4 questions was designed in order to probe student thinking by eliciting detailed written responses. The questions required explanations that students (a) would be expected to know from prior teaching and (b) had not been taught formally. The latter thus required students to come up with their own explanatory ideas. The instrument was administered to group of 87 introductory astronomy students.

This poster presents details of the instrument and selected results from the analysis of student writing. The analysis indicated that the central idea(s) the students used to underpin the reasoning for the phenomena they had been previously taught were largely in agreement with the accepted astronomical explanations. However, the way in which the students expressed these central idea(s) was surprisingly diverse. This highlighted the fact that diversity of thinking amongst a student cohort is masked when the focus is placed only on the summative outcome. With regard to the questions that probed areas that had not been formally taught, the key observation was that the majority of students drew on ideas that were plausible. Additionally, even where the ideas expressed did not coincide with the concepts that are central to the canonical explanation, it was clear that “sensemaking” was driving student reasoning.

The Impact of Astronomical Based Outreach for Inspiring Young Minds in Debre Berhan, Ethiopia.Abel T. Sisaye, Gizaw B. Yitayew, Abubeker S. Ali, Awoke Tadesse, and Getachew Tesfaye

Mr. Abel T. Sisaye

Debre Berhan University, Ethiopia

Abstract

The Ethiopian Space Science Society (ESSS) - Debre Berhan University (DBU) Branch is one of the earliest established branches of ESSS. For the past 15 years, the branch has conducted remarkable outreach activities. These activities aim to ignite a passion for Astronomy and Space Science among DBU and local high school students through a variety of engaging methods, such as Q&A contests, creativity and innovation contests, stargazing sessions, public talks, documentary screenings, lecture series, and hands-on workshops on rocket and satellite model building, and celestial photography. The goal of these efforts is to inspire young minds and foster a love and respect for science in Ethiopia. This initiative was deemed necessary due to the observed trend among Ethiopian youths, and globally, where students in high schools and universities show limited interest in science, particularly physics. Using astronomy as a tool for inspiration, although not new, has proven effective again here in our society, thanks to the substantial efforts of the society's executive committee. The results of these efforts have been profoundly encouraging: a significant number of DBU students from diverse academic backgrounds have developed an appreciation for science in general, with a notable increase in interest in pursuing advanced studies in Astronomy and Astrophysics. Furthermore, high school members of the society have shown a marked increase in their enthusiasm for science, demonstrating the program's effectiveness in fostering a culture of curiosity and innovation.

25 Years Thaqeb astronomy community activists

Presenter Hosna Fadaei yekta kaldehi

Thaqeb astronomy community

Abstract

This is a scientific report about the Thaqib Gilan Astronomy Association Acitites for 25 years in Iran. The Thaqib Gilan Astronomy Association began its journey, aiming to spread excitement about space in Iran's Gilan province. Back then, there wasn't much focus on teaching astronomy, so this association stepped up to fill the gap, especially in areas where learning resources were scarce.

The association made sure everyone could join in, not just students and teachers but anyone interested in stars and planets. They wanted to create a friendly space where people could learn and have fun together.

Their goal was clear: to change how people learn, with the help of enthusiastic folks. They believed in working together, planning carefully, and keeping the excitement going. Even before they officially started, they were already making waves with their activities.

The Thaqib Gilan Astronomy Association marked the beginning of a big change in education. Over the past 25 years, they've made a real difference. More students and everyday folks are interested in astronomy now.

Exploring Indigenous Astronomy: The Kargahe Setare Project's Use of Iran's Cultural Heritage for Astronomy Education

Shahrzad Mirsoltani

Director and Astronomy Educator at Kargahe Setare Project. Member of Zaferanieh Educational Observatory. Writer and Educator at Nojum Magazine. Member of the Specialized Science Group of the Children's Book Council of Iran. Writer and Member of Astronomy Group of Experts of Iranian Encyclopedia for Young People and Children. Expert and Podcaster at SpaceStation Podcast

Abstract

Astronomy stands out as one of the oldest sciences cultivated by humanity. Iran, as one of the most ancient countries, holds a rich heritage that has been globally recognized for centuries. Throughout history, people have gazed upon the night sky, and the reflection of their astronomical observations can be seen in various formats. These celestial objects, such as the moon, sun, and stars, have manifested in different ways in Iran's heritage, such as pottery, coins, manuscripts, and instruments. Indigenous astronomy has emerged as an important issue in the field of astronomy education and outreach in today's world. To address this issue, the Kargahe Setare Project undertook extensive research to explore the visualization of the heavens in Iran. By gathering objects from Iran's heritage and creating a database, the project utilized the visualization of the heavens to produce novel educational astronomy content for younger generations. This project offers a compelling example of how ancient heritage from different countries can be employed to create educational resources. By leveraging this heritage to disseminate knowledge about astronomy, history, culture, and art, we can transfer the legacy of our past to the present and future generations.This work can inspire researchers, Educators, Science Promoters and Scientists worldwide to explore their own country's cultural heritage in astronomy, history, culture, and art. By examining these fields together, we can gain a deeper understanding of our shared human experience.

Empowering Namibian Astronomy: Students Driving Outreach, Research, and Innovation

Mr Hiiko Katjaita

University of Namibia

Abstract

This abstract offers a unique perspective on Namibia's astronomy landscape, emphasizing students' significant contributions while addressing inclusivity, accessibility, research excellence, and international collaboration. The University of Namibia's student-operated mobile planetarium program, recipient of the Annie Maunder Medal from the Royal Astronomical Society, led inclusively with undergraduate students from diverse academic backgrounds, has engaged over 12,500 individuals, primarily school children, bolstering national science education and sparking public interest in astronomy across Namibia and Africa. Undergraduate students have also led publications such as an article on 'providing insights into running a student-driven mobile planetarium project in Africa' published in the “Communicating Astronomy with the Public Journal”. Additionally, students, including undergraduates, actively contribute to cutting-edge research and telescope operations at facilities like H.E.S.S., particularly during times of limited international access like the COVID-19 pandemic, strengthening global research resilience. Furthermore, students play a key role in the development of the AMT, focusing on site selection, future capabilities simulations, and observational strategies, and raising public awareness through the mobile planetarium, fostering future workforce development. Moreover, students support astro-tourism efforts by participating and helping the Namibian Academy for Tourism and Hospitality host programs aimed at equipping tour-guides and the public with astronomy knowledge and assisting in stargazing activities, promoting astronomy appreciation among locals and visitors. Recognizing the role of students in astronomy development, this work promotes an inclusive and collaborative future for the field, showcasing the pivotal role that Namibian students play in the development of astronomy not only in Namibia but also across Africa.

A didactic experience in the study of the proper motion of stars in the classroom

Mr. Rafael Girola Schneider

Universidad Nacional de Teews de febrero. Planetario Galileo Galilei

Abstract

The proper motion of stars is a very important topic in an Astronomy course. In principle, it allows us to measure the spatial speed of the stars in relation to the Sun and, from this, determine distances and other stellar parameters, allowing us to probe the proximities of the solar neighborhood and the speed of the local stars in the galaxy. That is why a work carried out by the Physics teachers in the subject of Astronomy II of the “Héctor Medici” Institute is presented. The work unifies a historical view of how and what was interpreted in the year 1718 when Edmund Halley found that the stars Sirius, Arthur and Aldebaran moved in the sky more than half a degree since the observations made by Hipparcos, along with a didactic sequence. That is, where students, through actions, link their knowledge and previous experiences, with some question that comes from reality and with information about an object of knowledge, managing to differentiate the improper movements of the stars, in which the coordinates stars are affected to the same extent by the movement of precession, nutation and aberration of light, deducing that only the proper movement corresponds to the real movement of the stars. One of the examples that has been highlighted in class is the proper motion of Barnard's Star moving 10.2 00/year. One of the tools on which the work is based is the information from the Tycho catalog, as well as measurements made by Hipparcos and Gaia satellites.

The Role of SAT Astronomy Learning Center in the Development of Astronomy Education and Outreach in Southern Thailand

Ms. Nareemas Chehlaeh[1], Ms. Nusreen Masae[2]

[1]Faculty pf Science and Technology, Prince of Songkla University. [2]Kathu district Office, Phuket

Abstract

This article aims to present the role and importance of an astronomy learning center in the development of astronomy education and outreach in southern Thailand. The Science and Technology (SAT) Astronomy Learning Center was established at the Prince of Songkla University (PSU), one of the oldest universities in southern Thailand. The SAT Astronomy Learning Center has been continuously maintained and managed by the Faculty of Science and Technology since 2019. The initial purpose of constructing this center was to commemorate the Faculty of Science and Technology's hosting of the 2017 International Astronomy Olympiad. The center is divided into three parts, consisting of a planetarium room, an exhibition room, and a telescope room on the rooftop. The center has provided academic services, training, astronomy camps, monthly stargazing events, and crescent moon sighting activities to students, teachers, and the public. Fortunately, our astronomical activities were supported by Songkhla Regional Observatory for Public, which is under the National Astronomical Research Institute of Thailand (NARIT). The observatory provides academic services for the local communities and supports the implementation of astronomical curricula in schools and universities. It also serves as another astro-tourism landmark in southern Thailand. We argue that the role of the SAT Astronomy Learning Center will mainly support learning astronomy to enlighten all students and youths in science literacy. In addition, we mention the significance of astronomy as a part of the integration of science, technology, local culture, and life.

PopER Stand Up Científico: Between Science and Comedy.

Dr Juliana Saponara[1], Dr Aramburu Roxana[2], Dr Javier Garcia de souza[2]

[1]Instituto Argentino de Radioastronomía, CONICET-CICPBA-UNLP, CC5 (1897) Villa Elisa, Prov. de Buenos Aires, Argentina. [2]Facultad de Ciencias Naturales y Museo. Universidad Nacional de La Plata

Abstract

PopER Stand Up Científico is the first Latin American stand-up comedy group dedicated to scientific outreach. The group includes students, graduates, postgraduates, and scientific researchers, covering various disciplines such as biology, chemistry, biochemistry, biotechnology, **astronomy**, palaeontology, physics, and mathematics. The group originated from the first scientific stand-up comedy course, an initiative by Argentina's Ministry of Science, Technology, and Productive Innovation in 2015.

We developed individual and group materials to use stand-up comedy to demystify the stereotypical image of a strict scientist in lab coats and glasses. We focus on the personal lives of scientist and their relationship with their work. Simultaneously, we strive to communicate science by entertainingly presenting scientific concepts and ideas. Our goal is to captivate those who approach us, arouse curiosity in those unfamiliar with science, and echo with those already part of our community. The invitation is to laugh with us and at ourselves.

Our show is suitable for all audiences, and since 2015, we have consistently presented our performance in various venues in America, mainly in Argentina, including scientific meetings, planetariums, bars, and cultural centres. We were also in Ecuador and Uruguay and participated in online scientific conferences in Chile and México.

Comparison of Attitudes in Astrobiology and Science/Technology/Astronomy in Japan

Dr. Nobuhiko Kusakabe[1,2], Dr. Naohiro Takanashi[3], Dr. Masaaki Hiramatsu[2,4], Dr. Shio Kawagoe[3], Mr. Koki Sawada[5], Mr. Harufumi Tamazawa[3]

[1]Astrobiology Center, NINS. [2]National Astronomical Observatory of Japan. [3]The University of Tokyo. [4]The Graduate University for Advanced Studies, SOKENDAI. [5]University of Wakayama

Abstract

We surveyed the Japanese public's attitudes toward Astronomy (Takanashi 2023) and Astrobiology. This survey was conducted via an online questionnaire, and responses were received from 2000 general public people. Respondents were people aged 20–69, selected from monitors registered with the survey firm, and were assigned according to the demographic and regional distribution of Japan.

The survey items consist of sociodemographic variables and questionnaire items. The sociodemographic variables are AGE, GENDER (male, female, and other), LOCATION (prefecture), MARRIAGE (married or not), CHILDREN (have a child or not), EDUCATION (educational background), and OCCUPATION. Fifteen of the questionnaire items were related to the attitude of Science, Technology, and Astronomy. The other six items were related to the attitude of Astrobiology.

The first three items are prepared for measuring the degree of interest in science and technology based on the Victorian Segmentation method (Quantum Market Research 2008), which classifies the general public and discusses their properties at a higher resolution. The next twelve items are prepared for measuring the degree of interest in astronomy from several different point of views. The last six items were prepared for measuring the degree of recognition in astrobiology from some interdisciplinary topics. Many of these questionnaire items were newly proposed for this survey from the point of view of comparing with prior surveys and researches.

This poster will present the results of a comparison of Science, Technology and Astronomy interest groups and their attitudes of Astrobiology.

Astronomy Outreach Activities within the Context ofPLOAD (Mozambique Node)

Mr Edson Jequecene[1,2], Dr Valente Cuambe[3]

[1]Detetives do Cosmos - Amateur astronomy Group. [2]PLOAD (Portuguese Language Office of Astronomy for Development). [3]Department of Physics, Eduardo Mondlane University

Abstract

The Portuguese Language Office of Astronomy for Development (PLOAD) was established in August 2015 by the International Astronomical Union's Office of Astronomy for Development (IAU-OAD). In Mozambique, initial activities were primarily concentrated at Eduardo Mondlane University (UEM). During its initial phase, the program was supported by merely three volunteer researchers with specialised astronomy training. Among various projects undertaken, the Galileo Teacher Training Program (GTTP) was notable for its focus on primary education teacher training. Subsequently, UEM incorporated an introductory course on Astronomy into its Physics and Meteorology curricula, which catalysed several projects that significantly boosted interest in Astronomy within the country. Presently, numerous teams of science communication enthusiasts are spread across Mozambique, promoting Astronomy through lectures in schools, public spaces, and social media platforms. However, extending these educational and outreach activities to remote areas beyond urban centres remains a challenge due to resource limitations, with the capital predominantly benefiting from in-person activities. Moreover, securing funding for acquiring or constructing a planetarium, which would greatly enhance the dissemination of Astronomy and STEM (Science, Technology, Engineering, and

Mathematics) education in general, continues to be a significant hurdle for the organisation.

This work aims to present the progress of activities in Mozambique to

the international community.

The Monumental replica of the Antikythera Mechanism in Hermosillo

Dr. Julio Saucedo Morales[1], Dr Xenophon Moussas[2], Dr. Ezequiel Rodríguez-Jauregui[1], Eng Alfredo Carmona Martinez[3], Eng Jesús Clemente Olvera Trejo[3], Dr. Raúl Perez-Enriquez[1], Dr. Armando Ayala Corona[1], Dr. Alma Ayala Moreno[1]

[1]Universidad de Sonora. [2]University of Athens. [3]Relojes Olvera III Generación

Abstract

The Antikythera Mechanism (AM) was built by Greeks in the second century BC, lost to the sea around 70 BC and found near Antikythera in 1901. Motivated by the results of 120 years of research, scientists from Universidad de Sonora, University of Athens and *Relojes Olvera III Generación* (ROIIIG), embarked on a project to build two replicas of the AM (1:1 and 10:1) incorporating all known results. The 1:1 replica was presented in 2022. Thanks to the Sonoran Government on February 8, 2024, the 10:1 Monumental Antikythera Mechanism for Hermosillo (MAMH) was inaugurated, after 3 years of collaboration. MAMH (3.1 m in height, made of brass) is unique in the world. It is moved by a monumental clock built and donated by ROIIIG. In the front it presents in real time fairly correct positions of the Sun, the Moon (with its phase) and the 5 visible planets. In the back, the Saros spiral for the prediction of eclipses is below, whereas above is the Metonic spiral. Other small dials are also included. Though based on a geocentric model MAMH makes good astronomical predictions reinforcing the idea that the AM is an analogous computer, perhaps the first in history. MAMH is in the *Antikythera Plazoleta* at Universidad de Sonora. The aims of the MAMH project are Astronomy Education and Outreach. School groups of all levels, families, and public are welcome. People around the world will also be able to see the predictions via Internet thanks to cameras pointing at MAMH.

It's not just money: The Economic Barriers to Amateur Astronomy

Dr Pamela Gay[1], Dr Sanlyn Buxner[2]

[1]Planetary Science Institute. [2]University of Arizona

Abstract

We examine what economic factors prevent participation in amateur astronomy through survey data. It is anecdotally understood that amateur astronomers in the United States are typically affluent men. While this is often considered the result of both the high cost of telescopes, and the challenges in implementing demographic change, it is unclear what else is at play, and what specifically needs to change to make amateur astronomy open to a larger and more diverse set of demographics.

This research will look at both at-home engagement and remote astronomy. We define at-home engagement as amateur astronomers having equipment on hand to use in the vicinity of their home, or to take with them for in-person use. Remote astronomy is defined as using equipment, either rented or owned, that is at a fixed remote location and can only be accessed via the Internet.

In the first part of the survey, we will ask about what kinds of amateur astronomy the survey participant would want to learn and do if financial constraints (including factors such as working multiple jobs or providing child or elder care) were no barrier.

In the latter half of the study we explore what are the possible time and monetary outlays that people can spend on astronomy-related activities and how these compare with their perceived costs of astronomy.

We will also ask survey respondents about their local sky conditions, their access to the sky, and basic demographics, such as state, age within bins, pronouns, and areas of work.

Survivors Guide to New Media: Reaching audiences across multiple platforms

Dr Pamela Gay[1], Avivah Yamani[1,2]

[1]Planetary Science Institute. [2]Langitselatan

Abstract

A key factor in public outreach is going where the public goes. This means, as new technologies take hold, astronomy communicators must step forward as early adopters to make sure we can stake out our place to take about the stars in a landscape of memes, news, and too often hate. We are, with our science, a safe island in a sea of social media.

We will highlight the differences in platforms, review the literature on how people are using these platforms to communicate to massive online audiences, and we will discuss new results from a survey that looks at the distribution of our audiences across content platforms. With this data in hand, we present on the tools that can be used to make reaching all the different audiences as straight-forward as possible. This includes the ethical use of AI to add in content editing and repurposing.

Rethinking astronomy in conflict contexts and war anxiety

Dr. Mirjana Povic

Space Science and Geospatial Institute (SSGI), Ethiopia

Abstract

We are facing difficult times in which heavy wars and conflicts are affecting different parts of our planet and are putting into question our morality and what we have learned as humanity from the past and from our previous mistakes. Many countries in Africa are not excluded from political instability, conflicts or wars, and violence that has become normalized. Under such conditions, education and science are strongly affected. We rarely talk openly about how, under conditions of conflict and war anxiety, intense fear, constant stress, persistent worry, and hopelessness, astronomy research and education can be performed. Under such conditions, "What is the role of astronomy in making our world a better place?" becomes a real and challenging question that needs much rethinking. This talk aims to give more visibility to the challenges we face when we do research and teach astronomy in conflict contexts. It also aims to remind us that, in such contexts, astronomy must be used more than ever to constantly transmit the message that we all live under the same sky and to promote peace-building. This talk will also provide a list of recommendations on how we as a scientific community can support our colleagues and students working and living in conflict-affected areas, and will open the space to think about new initiatives by providing a list of suggestions.

Cultural Astronomy for Sustainable Development: A study on Indigenous San Communities in Botswana and Namibia

Ms. Tumo Fortunate Kedumele[1,2], Dr Auala Sisco[3], Ms. Maaike Perik[4,5], Ms. Keletso Bontle Dichaba[1,2]

[1]Botswana International University of Science and Technology. [2]Women in STEM-BW (WiS). [3]Namibia University of Science and Technology. [4]Radboud University. [5]University of Namibia

Abstract

This study explores the cultural astronomy knowledge of the Basarwa/San and Bangwato communities in the Central District of Botswana, as well as the Ju/'Hoansi San community in North-Eastern Namibia. The research was conducted in collaboration with the Central Botswana San community in Moralane village, the Bangwato in Serowe-Paje villages, and the Ju/'Hoansi community in Namibia. The San communities are widely recognized as the indigenous and native people of Southern Africa, possessing a wealth of raw and untouched knowledge of the history of astronomy within a Southern African context.

The primary objective of this study is to gain insight into how astronomy and the celestial realm influence the culture, history, and daily lives of these communities. Additionally, the study seeks to identify and establish connections and similarities between the Basarwa/San and Bangwato in Botswana and the Ju/'Hoansi community in Namibia.

The indigenous knowledge, along with folk stories collected during the first and second phases of this study, were meticulously recorded, interpreted, and subsequently compared and correlated with modern astronomy. The purpose of this knowledge-matching process was to establish a relationship between astronomy and modern astronomy, highlighting how both can contribute to the socio-economic development of these communities.

Astronomy Centre for Educators at IUCAA: An experiment to improve pedagogic processes in Indian colleges and universities

Professor Dhruba J Saikia

Inter-University Centre for Astronomy and Astrophysics (IUCAA)

Abstract

The Astronomy Centre for Educators at IUCAA was established in 2018 with the objectives of contributing to improving pedagogic processes in Indian colleges and universities. We have had a wide range of programs for the last six years which could be divided into five broad categories. Firstly we have emphasized development of expertise in astronomy-themed experiments, where we are building a repository of experiments with contributions from across the community. As an example of an experiment, faculty members have designed a horn antenna, made observations of neutral atomic hydrogen in our Galaxy, taken the equipment to their host institutions and done projects with these. Secondly, we have had courses with lectures, hands-on components, tutorials and assignments spread in the evenings over two to three months to enable faculty members to learn slowly while continuing to teach. Thirdly we have had focused short-term workshops emphasizing the hands-on components, and where teachers also share experiences and discuss how to teach a particular topic better and also make presentations on topics they are teaching or likely to teach. Then we are collaborating with the Maharashtra State Faculty Development Academy in India to conduct workshops in small towns on the theme of Astronomy, Science and Society to take the excitement of astronomy to faculty members across disciplines. Lastly we are focusing on orientation and sensitization programs for the new National Education Policy being implemented in India. This paper presents the results, our experiences and challenges.

Preserving the Past, Illuminating the Future: INAF Mission to Safeguard and Celebrate Italian Astronomical Heritage

Federico Di Giacomo[1], Antonella Gasperini[2], Ileana Chinnici[3], Manuela Coniglio[3], Giangiacomo Gandolfi[4], Mauro Gargano[5], Salvatore Guglielmino[6], Francesco Poppi[1], Valeria Zanini[7]

[1]INAF - Osservatorio di Astrofisica e Scienza dello Spazio di Bologna. [2]INAF - National Institute for Astrophysics. [3]INAF - Osservatorio Astronomico di Palermo. [4]INAF- Osservatorio Astronomico di Roma. [5]INAF - Osservatorio Astronomico di Capodimonte. [6]INAF - Osservatorio Astrofisico di Catania. [7]INAF- Osservatorio Astronomico di Padova

Abstract

One of the statutory missions of the National Institute for Astrophysics (INAF) in Italy is the protection, conservation, and enhancement of the huge historical heritage that is preserved in the astronomical Observatories. This important heritage offers unique opportunities to develop research in the History of Astronomy and foster interdisciplinary investigations in Cultural Astronomy. In this contribution, we aim to briefly describe the INAF historical collections, which consist of instruments, books, artworks and archives, mostly dating back to the 18th and 19th centuries. Thanks to the project “Polvere di Stelle” (Stardust), INAF has created a web portal (https://www.beniculturali.inaf.it/) dedicated to the Italian astronomical libraries, archives and museums. It offers various tools and databases designed to support astronomical research and increase the value of one of the richest astronomical heritages in the world. Most importantly, this project allows the connection of heritage from different observatories to tell a unified story.
We mention the recent "Touch Sky", a project including research, restoration and fruition of historical celestial atlases. Some bicentenaries of the birth/death of reputed astronomers, such as Secchi and Respighi, are also providing the opportunity to study and restore some instruments, books and archival documents related to their scientific research.

Looking forward to IAU GA 2027 in Rome, it is our hope that activities for the study and enhancement of the INAF astronomical heritage will encourage links with cultural astronomy activities in Italy and abroad; the “Seconda Stella a Destra” project, for instance, has developed “astrotourism” in historical Italian towns.

'Astro Ecology': Exploring the Scientific and Social Interaction Between Celestial Bodies and Earth's Ecosystems, Astronomical Influence and Solutions to Combat the Negative Effects.

Ms. Anupama Rajya Shahi

Eco-Heart. Central Department Of Environmental Science, Tribhuvan University. Nepal Academy Of Science ans Technology (NAST)

Abstract

Astronomy has the power to restore harmony and vitality to our blue planet.

Astronomical instructions currently taught needs to be swiftly and significantly revised.

Numerous challenges, such as climate change, ecological disruption, imbalances in flora and fauna, inadequate food production with inconsistent nutritional values, health risk, bacterial-viral alternations beset us in our everyday lives and must be addressed with seriousness.

More practical teaching like harnessing energy, its proper utility, astronomical effects on earth and finding solutions to problems vexing us that bear interactive relations to our Sun, Moon along with all the planets in our Solar System and Galaxies.

Promoting interactions with contemporary technical instruments by leveraging digital and AI applications with reliable internet helps to reduce the conflict and unhappiness that permeate our scientific and social environment. More team efforts, young generation engagement, adequate financing responsibly by all of us together for all these efforts essentially needed to unravel the secretive enigmas and mysteries bestowed by nature that bear charismatically arcane relations with astronomy.

Participations in Space explorations should be encouraged to all interested members and citizens of our planet. Astronomers and astronauts could attempt to establish strong networking-bond among humans upholding positive supportive values of humanity to respect and learn from each other for surmounting any problems in efficient and elegant manner. Impending hazards and lurking dangers from space could be identified for mitigating and avoiding them. Interactions with academic institutions in research, applications should be even more facilitated and strengthened.

Short stories - *A Collection of African Astronomy Tales.*

Dr Ann Njeri[1], Tabitha Alango[2]

[1]Newcastle University. [2]Masai Mara University

Abstract

In many places in Africa (particularly in rural Africa), Astronomy is seen as an exotic science belonging to the West. To address this misconception and make Astronomy more relatable, Elimisha Msichana Elimisha
Jamii na Astronomia (EMEJA) organised a workshop in Kitale, Kenya, targeting high school teachers and the locals. The objective was to discuss and document Astronomy application and stories in the African context from back in time. For example, what were the cultural beliefs with regards to creation of the Universe? Different communities in Kenya have different ideas and beliefs on how the Universe, the earth, the sun, stars and moon were created. Our target audience were diverse and coming from different communities, and therefore provided diverse Astronomy-related tales that were nicely documented. Here, I will share some of these tales. For example, the Kikuyus believed that all the demons were sent to irima iruku (Kikuyu for a bottomless hole) where they could never escape. This being a likely reference to a black hole. The aim was to build upon these reflections and to use the ideas generated to effectively deliver Astronomy-related content in classrooms as part of the curriculumn for secondary education in Kenya. Overall, we aimed to spur interest in and appreciation of Astronomy across the whole community.

Enhancing Astronomy engagement: AfAS Strategies and Outcomes

Ms Zodwa Tiki

African Astronomical Society (AfAS)

Abstract

At the International Astronomical Union General Assembly (IAU-GA2024), it is crucial to recognise the complexity of public communication, where the audience is expected not only to comprehend astronomical concepts but also to actively participate in discussions and dialogues. The African Astronomical Society (AfAS) strives for effective communication with a focus on information sharing, knowledge transfer, and education, which are the primary objectives. Publications, including newsletters featuring compelling articles on astronomy and AfAS conferences and workshops, serve as key platforms for disseminating information and fostering community involvement.

The Newsletters have had a tangible impact on the public as they serve as a bridge between the astronomical community and the wider public, fostering understanding and interest in astronomy-related topics. Recognising the importance of online visibility, AfAS has invested in enhancing its website's user experience and regularly updates its content to provide valuable resources and information. Our efforts on social media have also yielded promising results, significantly expanding AfAS's outreach with notable increases in engagement metrics.

Moreover, AfAS actively participates in conferences, meetings, and oral communication to reach wider audiences and facilitate dialogue within the astronomical community and beyond. These gatherings serve as invaluable platforms for exchanging knowledge, fostering collaboration, and advancing scientific understanding. In essence, the strategies implemented by the AfAS Communications Committee foster dialogue and engagement, ensuring that the public not only comprehends astronomy but also becomes empowered to participate in meaningful discussions.

Formal education of Astronomy at School and College level as an extra curricular activity through Public Private Funding

Dr. Mukund Kurtadikar

Department of Physics, J.E.S.College, Jalna 431 203, India

Abstract

At present there is no formal channel for providing formal education of Astronomy at School and College level. However, somewhat similar work is being done through various activities of NGOs of amateur astronomers and outreach programmes conducted by various National Institutes, not in a well organised manner. Therefore there is a need to provide a channel for providing formal education of Astronomy at School and College level with a view to create general awareness as well as Human Resource. This can be achieved through dedicated efforts for this purpose though Public - Private Funding .

Formal education of Astronomy of various levels like proficiency, certificate and diploma level could be imparted by the schools and colleges as an 'extra curricular activity' run by a club formed for this purpose, in the scools and colleges. However, curriculum for this purpose be formulated by academic organisations /institutions and implemented by the 'clubs' in their schools and colleges. The clubs would be affiliated to the 'Outreach Departments' of the academic organisations /institutions in the country. Each school /college participating in this scheme should procure small observing telescopes through PPF i. e. donations and the activities run by the club so that the curriculum could be implemented more effectively. Moreover, the observing facilities could be used for dedicated 'amateur activities' of professional level by contributing their observations in 'observing campaigns' run by international organisations. In fact contributions of such observations could enrich the campaigns, which is also the need of the time.

The TART workshops: Building an African Education and Outreach Network of Radio Telescopes

Dr Tim Molteno[1,2], Dr Ben Hugo[3], Professor Oleg Smirnov[4,3], Dr Nadeem Oozeer[3], Dr Max Scheel[2]

[1]University of Otago, Dunedin New Zealand. [2]Electronics Research Foundation, New Zealand. [3]South African Radio Astronomy Observatory. [4]Rhodes University, Makhanda, South Africa

Abstract

The Transient Array Radio Telescope (TART) is an open-source, low-cost, compact imaging radio telescope developed by a dedicated community of volunteers from both the general public and the radio astronomy community. In Africa, South African Radio Astronomy Observatory (SARAO) and the TART project have developed the idea of building a self-sustaining outreach and education network through TART workshops: week-long workshops, in which volunteers from the TART project teach the fundamentals of radio astronomy in the mornings, and build a functioning radio telescope in the afternoons. The TART telescope remains at the host institution, and becomes a focus for outreach within that community, and also a common platform for collaboration in teaching and research between members of the TART network. Attendees can then present at future workshops, bringing their unique perspectives, developing links between communities and building awareness of the radio sky.

TART workshops in 2023-25 include South Africa, Botswana, Namibia, Zambia, Ghana, Mozambique, Mauritius and Madagascar and Morocco, and in the near future, the TART network will expand out of Africa, with workshops planned in Iran, Malta, and the USA.

INVESTIGATION OF BANGWEULU BASIN AS A POSSIBLE CANDIDATE FOR A METEOR IMPACT, ZAMBIA

Mr Omogolo Keobokile, Dr Prospery Simpemba, Dr Edward Chisakulo, Dr Moola Mutondo

The Copperbelt University

Abstract

The Bangweulu Basin in north Zambia has previously been proposed as the site of a large (150km diameter) impact structure on Zambia's Bangweulu Block (centered at 11°10'S, 29°54'E). The Bangweulu Swamps, Lake Bangweulu (85km long), and Kampolombo (20km long) are all located at about 1148m above sea level (a.s.l). The Bangweulu Basin is a centripetal drainage system, with one outlet in the south, the Luapula River and the other outlet in the southwest is Luasenshi River. The Bangweulu Basin is largely aseismic and unconnected to rifting, in contrast to all the other significant lakes in Zambia and the neighboring regions (Mweru, Tanganyika, Rukwa, Malawi, and Kariba), which are located in seismically active rift structures. In addition to a magnetic anomaly density high over the center of the Bangweulu Basin, which is encircled by a concentric low, there is a positive aeromagnetic intensity anomaly over the central Bangweulu depression. Lake Bangweulu is in the middle of a nearly spherical anomaly of the local Bouguer gravity field, which is bounded by an arcuate high south of the Luongo Fold Belt and defined by the -140mgal contour. Lake Bangweulu's genesis is still unknown, some scholars proposed that it was by a meteorite impact, Master (1993). This is an ongoing research which is aimed to be concluded by June 2024, ground search has been conducted and rocks samples have been conducted. Laboratory analysis is ongoing and after conclusion will be made on whether to prove or disprove that this as a carter.

Review of Astronomy and Space science Developments in Zambia

Mr Ashley Nyamandi[1], Mr Prospery Simpemba[2], Dr Saul Phirii[3]

[1]The Copperbellt University. [2]The Copperbelelt University. [3]Copperbelelt University

Abstract

Zambia has made remarkable progress in the area development of astronomy, human capital development and strengthening of academic and learning programmes at institutions of higher learning. Several activities have been implemented in this process. In this talk, we highlight key developments that have taken place and forecast the future of astronomy and space science in the country. We touch on new learning programmes that have been developed, the training activities including but not limited to Development in Africa with Radio Astronomy (DARA), starlight in the university lab (ASTROLAB), Network for Astronomy School Education (NASE) and several other astronomy workshops done over the years. The country has been doing several outreach programmes to inform the public about astronomy's importance and the benefits of hosting an observatory of the Square Kilometre Array (SKA) project at Kasempa, now called the Kasempa Radio Astronomy Observatory (KASERAO).

Taking the universe to the community

Miss Tshepiso Maroga

Sci-Enza Science Centre, University of Pretoria

Abstract

Everyone should have the chance to acquire astronomy knowledge, a valuable heritage that should be accessible to all. Sci-Enza is committed to providing astronomy education to individuals from underprivileged backgrounds, those encountering socio-economic obstacles, and those with special learning requirements, without any limitations.

To ensure broad access to astronomy, we align our astronomy programme with the National Curriculum and Assessment Policy Statement (CAPS). We offer educational support in local schools and share general knowledge with the public through talks, planetarium shows, and workshops. National initiatives such as National Science Week and Programmatic Support Grant further enhance our astronomy outreach endeavors.

In this paper, we will share our experiences, successes, challenges, and recommendations in the astronomy outreach

Engarium: Empowering Astronomy Outreach in Iran

Mr. Mohammad Hadi Tabatabaei Yazdi

Engarium Planetarium. Ferdowsi University of Mashhad

Abstract

Engarium, a groundbreaking initiative in Mashhad, Iran, stands as a testament to the transformative power of grassroots efforts in advancing astronomy education and outreach. In this abstract, we present a concise overview of Engarium's journey, focusing on its pivotal role in promoting scientific curiosity and literacy within the region. Despite facing formidable challenges such as economic constraints and governmental restrictions, Engarium has emerged as a beacon of hope, offering a low-cost yet high-impact platform for engaging with the wonders of the universe.

Through strategic fundraising endeavors and innovative architectural design, Engarium has defied conventional limitations to create a truly immersive planetarium experience. Key features such as the imposing meridian gnomon and the subterranean construction underscore Engarium's commitment to pushing the boundaries of traditional planetarium design.

Engarium's success is not merely measured in numbers but in its profound impact on the community. With over 100,000 visitors and a robust membership base of 14,000, Engarium has become a focal point for science popularization in the east of Iran. By democratizing access to scientific knowledge and nurturing a culture of curiosity, Engarium serves as a catalyst for social change and intellectual empowerment.

In this lecture, we reflect on the lessons learned from Engarium's journey, highlighting the resilience, creativity, and collaborative spirit that have fueled its success. As we look towards the future, we envision Engarium as a model for sustainable and inclusive astronomy outreach, inspiring similar initiatives worldwide and paving the way for a more scientifically literate society.

Song Lines to the SKAO: Listening Beyond the Darkness

Prof Deborah Kala Perkins

Ubiquity University. AAS, COSPAR

Abstract

As SKAO touches “First Light”, it is shape-shifting on lands of Earth’s most ancient cultures, like the Aboriginal Rainbow Serpent naming all creatures and creations of our Earth. Might not secrets the SKAO has to reveal shed light on mysteries of life’s emergence? This presentation explores root cultural heritage around the journey into darkness, from Australia and South African cultures, and our astronomical science. Southern cultures share appreciation of Milky Way’s “dark constellations”, and *sky rivers of stars*. We also explore the Hindu cosmologies of Great Darkness, beyond the days and nights – Manvantaras and Pralayas – of cosmic cycles. Scientific American Magazine began its 2024 issue with the story of Cosmic Voids. What are the roles and significance of darkness in these cultures where the SKAO is employing the longest radio frequencies to peer into our cosmic origins beyond the visible? How is SKAO’s journey into the darkness mirrored in the cultural stories; *Song Lines*, the undulations of the Rainbow Serpent’s sky music singing Earth and stars to life? We explore astronomical and cultural resonances, proposing a series of multimedia performances and artworks, - theater, dance, storytelling, painting, sculpture - sharing SKAO’s astronomical emergence, destiny and legacy with the peoples and cultures where it is embarking on its journey into infinity. This syncretic emergence is a cultural weaving at the curvature of SKAO’s awakening with ancient cultures in which it is located. Do scattered clusters of SKAO antennae reflect star clusters and galaxies, the space they are designed to fathom? We co-create.

Desertification and global warming

Hassan Baghbani[1], Fatemeh Baghbani[2]

[1]ITAU. [2]Boushehr astronomy community

Abstract

Our research and findings, in the mountains of Southwest and Central part of Asia,North and Northeast part of Africa, and the Andes Mountains, in South America, show that, since thousands years ago, peoples by making billions of water dams (traces farming)and planting trees, they have had mead the biggest desertification, and by planting trees in millions of square kilometers, they created suitable vegetation and sufficient humidity that caused decrease the weather temperature .
Why this mechanism was very useful ? Because

1-The roots of the Trees have also made the dams stable. 2-The roots of the trees, penetrating into the ground, have created enough space for water to sink into the ground.
3- every year, with the fall of leaves, the quality of the soil has improved and cover the soil
4- the trees shadow on the ground, have prevented the soil and stones from heating up,
5- the leaves of the trees have caught the sun's rays, and stored them in the trees body,
So controled the temperature.
This great work has been in the form of a holy job.
Unfortunately, in recent centuries, with the industrialization of societies, these dams have been abandoned, which has resulted in severe soil erosion, and a decrease in vegetation, a severe decrease in vegetation, and the desertification of a large part of the land, one of the The important factors are global warming

Astronomy outreach roadmap for Zambian

Mr Chidi Joseph Nicholas, Mr Prospery Simpemba, Dr Saul Paul Phiri

The Copperbelt University, Department of Physics, P.O. Box 21692, Kitwe, Zambia

Abstract

Outreach activities have been instrumental in creating awareness about astronomy in Zambia. Many activities have been conducted, including but not limited to, sensitization for safe viewing of solar eclipses, science festivals, targeted school visits, naming of exoworlds, among other public engagements. The country launched the national outreach programme on 8th December 2023 which will see an intensified but strategic public engagement. The roadmap rides on other projects that have been identified and which render high potential to reach out to a wider public.The National Outreach Committee (NOC) has been reinforced by incorporating new volunteers to the existing team, among them postgraduate students. This presentation will highlight new ways and best practices in which public engagement will be carried out in Zambia.

The Cosmos as a Classroom: Reducing Anxiety through Astronomical Wonder

MR Dominic Vertue, Dr Joyful Mdhluli, Mrs Mampho Ledimo

OAD

Abstract

In this exploration, we propose to utilize the captivating appeal of the cosmos as an innovative educational framework for reducing anxiety, particularly among young learners. By integrating astronomical content into learning environments in a way that emphasizes curiosity, wonder, and the joy of discovery, we aim to create a more engaging and less stressful educational experience. We will examine the link between the natural human fascination with the stars and the potential for such interest to alleviate feelings of academic pressure and anxiety. The theory supporting our approach suggests that engagement with awe-inspiring subjects like astronomy can elicit positive emotions that counteract stress and anxiety, thereby fostering a more relaxed and conducive atmosphere for learning. Through this initiative, we seek to demonstrate how the vastness of the universe can offer a comforting perspective on personal challenges, making the educational journey a more inspiring and less daunting experience.

Astronomy, Space Science and Technology Education at the African Regional Centre for Space Science and Technology Education

Prof Babatunde Rabiu[1], Dr Bonaventure I. Okere[2]

[1]United Nations African Regional Centre for Space Science Technology and Education - English, (UN-ARCSSTE-E), Obafemi Awolowo University Campus, Ile-Ife, Nigeria. [2]Centre for Basic Space Science, National Space Research and Development Agency, Nsukka, Nigeria

Abstract

In line with the implementation of the United Nations General Assembly Resolution 45/72 of 1990 and 50/27 of 1995, The African Regional Centre for Space Science and Technology Education in English (ARCSSTE-E) was inaugurated in Nigeria on 24th November 1998. The Centre has continued to implement its mandates particularly in the building of African indigenous capacities for the development and utilization of Space Science and Technology through its postgraduate programmes, short term trainings, outreach and research activities. From inception in 1998 to date, ARCSSTE-E has graduated six hundred and twenty four (624) Postgraduate Diploma (PGD) participants from nineteen (19) Anglo-phone countries in the following application areas namely; Remote Sensing/GIS, Satellite Communication, Basic Space and Atmospheric Science, Satellite Meteorology, Global Navigation Satellite System (GNSS) and Space Law. Astronomy is taught as a course to students with interest in Space and Atmospheric Science. The Centre is presented as model for postgraduate training in Astronomy. A call is made for collaboration and support from organisations with interest in capacity development on Space Science and Technology Education in the developing countries.

Development and Testing An Android-Based Virtual and Augmented Reality: A Platform for Teaching Abstract Astrophysics, Concepts and Experiments.

Mr. Gabriel Paul

University of Nairobi. Development in Africa with Radio Astronomy- DARA

Abstract

As a result of the paradigm shift and transitions in teaching and learning, it is of necessity to incorporate information technology as an essential tool in education. Worldwide, Institutions of higher learning are applying the digital e-learning tools and mechanisms to enhance teaching aids for educational purposes, due to the fundamental change into the fourth industrial revolution. Therefore, it calls for a prompt response and action, through STEM implementation, to counteract the significant problems faced by educators in the teaching and learning environment. Consequently, the digital practical concepts that are visually presented to learners using digital media devices and computer-based interactive platforms come in handy to salvage these problems. These platforms include; Virtual Reality (VR), Mixed Reality (MR), Augmented Reality (AR) and Extended Reality (XR). This paper focuses on the development process and final output of an android mobile VR and AR application that is relevant to Science, Technology, Engineering and Mathematics (STEM) education, fit for purpose. Not long ago, Higher Education Institutions (HEIs) have been exploiting virtual and augmented reality technological avenues to convey abstract concepts via this flawless approach, thereby enhancing the learning process. A virtual and augmented reality platform was developed. Students interact with the VR and AR multi user and 3-Dimensional (3-D) virtual rooms that looks like they're in real life-virtual environment. As a recommendation therefore, the infinite possibilities of virtual and augmented reality may be explored by educators, due to the comprehension of imagined concepts of its seamless-enabled simulations, and specifically in STEM education.

Teaching Indigenous astronomy in Ethiopia

Dr Getinet Ayane

Kotebe University of Education. Ethiopian Indigenous Knowledge Education and Research Center

Abstract

The cultural astronomy is among the least investigated in Ethiopia. Even though modern astronomy in Ethiopia is a recent history, astronomy cannot be entirely new in the country. Ancient agricultural practices, myths, calendars, alphabets, etc are quiet rich in astronomy. In the distant past the knowledge of astronomy was abundant. Ancient Books such as the book of Enoch, Bahire Hasab, Metsehafe Hasabe Berehan and Abu Shaker are devoted to this knowledge. The country has its own calendar, which is a witness for the existence of indigenous knowledge in astronomy.

There is a need to unearth indigenous astronomy in the country and to bridge the gap between cultural and modern astronomy. This abstract highlights the current status of indigenous knowledge of astronomy in Ethiopia, specifically some of the work I have started by publishing books on Ethiopian indigenous astronomy, the effort I did to reach the community through different media including television and the need for incorporating it in the modern curriculum.

Astronomy Education and Outreach using Mobile Planetarium at CBSS-NASRDA, Nigeria

Mr. Peter Okagu, Dr. Bonaventure Okere, Dr. Nnaemeka Onyeuwaoma, Mr. Timothy Egbuim

Centre for Basic Space Science and Astronomy (National Space Research and Development Agency) Nigeria.

Abstract

Planetariums are an essential tool in astronomy outreach, and their importance can never be overemphasized. The use of planetariums in astronomy and space science outreach has played a significant role in space science awareness. The Centre for Basic Space Science and Astronomy (NASRDA), Nigeria, has used its mobile planetarium over time to host educational outreaches to the awe of the participants. In the series of these events was the Astro-Christmas outreach for kids under the age of 15 years old. The event had 120 participants, with a gender classification of 70 girls and 50 boys. The content of the event includes outdoor lectures on the solar system, rockets, and women in space science. Inside the planetarium, space movies were played on solar system planets and their various distances, the moons, space travel, and a view of the International Space Station. The outcomes of the project were accessed using pre- and post-test surveys, which showed a significant increase of over 50% in the knowledge of space science and astronomy at the end of the event. Also, the qualitative assessment showed increased interest in space science and a willingness for increased participation in Science, Technology, Engineering, and Mathematics (STEM). Over time, the use of planetariums for space science and astronomy outreach has helped answer a lot of participants' questions. The planetarium at CBSS-NASRDA has been a point of attraction in the country, as schools, religious institutions, tourists, and enthusiasts are always eager to visit and satisfy their curiosity about its content.

Astronomy Education Concept Inventories: A Comprehensive Review

Dr Tshiamiso Makwela

IAU Office of Astronomy for Education. Max-Planck Institute of Astronomy / Haus der Astronomie. University of Cape Town

Abstract

This paper reviews astronomy concept inventories that have been developed and used in astronomy education. Concept inventories are tools that have been developed to measure students' conceptual understanding of concepts in astronomy and physics. These tools have been able to assist astronomy and physics lecturers and teachers in understanding their students better, thus creating learning materials that may help students develop more concrete learning experiences and knowledge gains. In most cases, these have been used as pre-test and post-test, where instructors are able to measure students' prior knowledge as they take the class and their learning gains at the end of the class/ course. Considering that most of these concept inventories have been developed and framed for entry-level undergraduates at universities, it is difficult to use these in primary and secondary schools. Since the content presented and learning outcomes of these widely differ, we need to find a way to tailor these concept inventories for primary and secondary schools. Additionally, while concept inventories provide good summative perspectives of what students know, they are also limitations such as the context, content, and their framing.

Analysis of the Practice of A Flipped Classroom Designed with ICE Model At A Japanese University Using Digital Diamond Mandala Matrix

Dr. Seiichiro Aoki[1], Mr. Shinzo Kobayashi[2], Mr. Takahiko Naraki[3], Dr. Hoichi Tsuchimochi[1]

[1]The Kyoto College of Graduate Studies for Informatics. [2]CCC-TIES. [3]GREEN-COLLOR

Abstract

We offer a course on the fundamentals of space and the universe for undergraduate students at a Japanese university. We will explain the practice of the course and its results of analyzing the students' summarized thoughts throughout the course to capture their stage in the learning process. We designed the course based on the ICE model developed in Canada. To facilitate their thought to transition from I (ideas) to C (Connections) and E (Extensions) in the ICE model, the classes consist of group work, group presentations, and discussions. We prepared course materials (e.g., PDFs and videos) so the students could learn in the flipped classroom. As the preparatory work, the students learn and gain knowledge from the materials(equivalent to I in the ICE model) and summarize their thoughts individually on the designated topic (e.g., habitation in the Moon) before participating in the group work. In the class, group members summarize their opinions as a group thought based on their thoughts prepared in the preparatory work, present them, and discuss them. After the class, they reconsider and recapitulate their thoughts on the same topic based on the in-class presentations and discussions. They used our digital Diamond Mandala Matrix (dDMM) to summarize thoughts. We compared the text data of their thoughts input before and after the class. Statistically, we analyzed them with the KH Coder to trace the transition in the learning process from I to C and E using verbs according to the ICE model.

PhD-level training on the interface of astronomy and computer science

Johan H. Knapen

Instituto de Astrofísica de Canarias, C/ Vía Láctea s/n, 38205 La Laguna, Tenerife, Spain.
Departamento de Astrofísica, Universidad de La Laguna, 38200 La Laguna, Tenerife, Spain

Abstract

Modern developments in fields like astronomy imply the need for advanced computational approaches to handle large data sets. However, most recent and current PhDs in astronomy have received little or no formal training in important areas including computer science, computational methods, software and algorithm design, or project management.

We will report on a number of scientific advances on the interface of extragalactic astronomy and computer science that have resulted from our EU-funded Initital Training Network SUNDIAL, in which 15 PhD candidates were trained. We will then discuss how these results will be built upon and expanded in a new Marie-Sklodowska Curie Doctoral Network called EDUCADO (Exploring the Deep Universe by Computational Analysis of Data from Observations). We will train 11 Doctoral Candidates in the development of a variety of high-quality methods needed to address the formation of the faintest observed structures in the nearby Universe, including novel object detection algorithms and object recognition and parameter distribution analyses of complex datasets. We aim to detect unprecedented numbers of the faintest observable galaxies from new large-area surveys. We will study the morphology, populations, and distribution of large samples of various classes of dwarf galaxies, compare dwarf galaxy populations and properties across different environments, and confront the results with cosmological models of galaxy formation and evolution. Finally, we will perform detailed simulations and observations of the Milky Way and the Local Group to compare with dwarf galaxies in other environments. Our interdisciplinary training tools, methods and materials will be made publicly available.

Breaking barriers to STEM careers through astronomy outreach and education activities

Dr Priscilla Muheki, Assoc Prof. Edward Jurua

Mbarara University of Science and Technology

Abstract

Education contributes greatly to science, technology, and innovation which are very vital in making societies a better place to live in.
Astronomy is known to be a powerful tool that can be used to promote education and science. In addition to that, it is one field of science that is envisioned to be a channel for technological developments, innovation and ultimately a tool to achieve the United Nations sustainable development goals especially for Africa. This is majorly facilitated by the significant growth of astronomy in Africa over the past years. This talk will summarise how we use astronomy during outreach activities to promote the love for school and education, science subjects and opt for STEM careers among primary and secondary school pupils in different schools in western Uganda through the support of the International Science Programme at Uppsala University. The biggest focus is on girls' schools as we hope to also break the myths surrounding girls excelling in science but we also include mixed schools and one boys primary school. I will also briefly talk about our efforts in training teacher trainees to teach astronomical concepts to their classes in secondary schools.

Transforming Access to Astronomy Heritage: Reorganizing and Automating Library and Archives Heritage Collections at Kodaikanal Solar Observatory

Dr. Arumugam Pitchai

Indian Institute of Astrophysics, Bangalore, India

Abstract

This research article presents a comprehensive approach to revitalizing access to the Astronomy Heritage collections at the Kodaikanal Solar Observatory (KSO) through reorganization and automation. The collection, consisting of books, journals, manuscripts, and observatory publications, holds significant historical value for Indian Science, with materials dating back to the 17th and early 19th centuries. The project aims to enhance the searchability and utilization of these resources by implementing modern cataloging techniques and automation tools. The study outlines the methodology and processes involved in reorganizing the library and archives collections, which includes leveraging advanced technologies for cataloging and metadata enrichment. The cataloging process entails creating detailed records for each item, incorporating descriptive metadata such as titles, authors, and subjects. Furthermore, the study highlights the use of automation tools like ATOM for Online Finding Aids and Koha for Library Automation to streamline processes such as indexing, classification, and retrieval of materials. The outcomes of this research contribute significantly to preserving and promoting the rich heritage of astronomy at KSO, ensuring that these collections remain accessible and relevant for future generations of researchers and enthusiasts. By employing modern cataloging techniques and automation tools, the project exemplifies a sustainable approach to managing and preserving valuable heritage collections, ensuring their continued significance in the field of astronomy and beyond.

LUIGI LILIO AUTHOR OF THE GREGORIAN REFORM OF THE CALENDAR

Prof. Sandra Savaglio[1], Prof. Francesco Vizza[2]

[1]University of Calabria. [2]Istituto di Chimica dei Composti Organometallici del Consiglio Nazionale delle Ricerche

Abstract

In the second half of the 16th century, the Julian calendar then in use since 46 BC marked March 21st as the day of the vernal equinox, but astronomically it fell on March 11th, about 10 days earlier. This was a serious problem for the Church which had linked the spring equinox to the fundamental mystical event of Christianity: the celebration of the Easter of Resurrection. It was in fact established that the Easter of Resurrection should be celebrated on the Sunday following the 14th Moon following the spring equinox. It was therefore necessary to correct the Julian calendar and prevent the spring equinox from falling behind the civil calendar, as had happened over the centuries. Luigi Lilio, Italian doctor, astronomer and mathematician, using old astronomical data contained in the Alfonsine tables, formulated a new idea: he eliminated ten days from the Julian calendar, synchronized the solar cycle with the lunar cycle and drew up a table of ultra-millennial validity (Cycle of the Epacts) which allowed the dates of Easter to be determined without uncertainty. The proposal was accepted by Pope Gregory XIII and since then, it was the year 1582, this has become the well-known universally accepted Gregorian calendar. This talk will be about a rather mysterious story that has almost disappeared nowadays due to the limited documents that have come down to us.

Introductory Astronomy students' notion of astronomical scales from a cognitive perspective offered by embodied cognition

Dr Tshiamiso Makwela[1,2,3], Professor Saalih Allie[3], Assoc Professor Dale Taylor[4,5], Assoc Professor Sarah Blyth[3]

[1]IAU Office of Astronomy for Education. [2]Max Planck Institute for Astronomy/ Haus de Astronomie. [3]University of Cape Town. [4]Department of Physics, University of Cape Town. [5]University of Cape Town, Center of Higher Education and Development

Abstract

Previous studies in astronomy education research in both South Africa and Norway indicated that students perform poorly on questions regarding astronomical scales. Despite the marked educational, language, and science education differences, the results for both were similar, which suggests that there is a possibility of deeper cognitive issues that impede the conceptualization of scales that lie beyond immediate human experience. We carried out an exploratory study using the grounded theory method, where we probed students' engagement with distances that vary from tangible (meters) to intangible (astronomical units, light years, parsec). We developed a short questionnaire that prompted written explanations regarding a specific distance category from the given distance spectrum and administered it to astronomy introductory students. A grounded analysis of the student's responses was done, and categories emerged, that showed students operating in different domains of thinking when dealing with distances. Moreso, the emergent categories showed to be consistent with other cognitive perspectives offered by embodied cognition. In this talk/poster, we will explore how embodied cognition can be used to frame aspects of astronomical scales.

Twenty Years of Advancing Astronomy Education, Outreach, and Development in Ethiopia: A Journey of Advancement and Collaboration

Mr. Biruk Terefe Getu

Ethiopian Space Science Society. Addis Ababa University

Abstract

As the Managing Director of the Ethiopian Space Science Society (ESSS), I am honored to present our organization's journey of two decades dedicated to the advancement of Astronomy in Ethiopia. Our efforts have been deeply rooted in the realm of Education, Outreach, and running developmental programs and projects. Over the past twenty years, the ESSS has tirelessly worked towards fostering a culture of scientific curiosity and exploration across Ethiopia. Our educational initiatives have spanned in all levels, encompassing both formal and informal education methodologies. We have collaborated with local educational institutions, governmental bodies, and international partners to develop Astronomy, established the Entoto Observatory and Research Center, and we are currently finalizing our site testing project at Lalibella in which we will build the biggest observatory in our region.

Through our outreach programs, we have endeavored to engage the wider public in the wonders of the universe. Utilizing diverse media and formats, we have brought astronomy closer to communities across Ethiopia, inspiring interest and appreciation for the cosmos. Our efforts in astro-tourism have promoted economic development, our training programs equipped our generation with the proper scientific background, and through our proactive engagement we made more than 1500 members and 30 branch associations. As we reflect on our achievements, we remain committed to advancing astronomy education, outreach, and development. During my presentation, I will illuminate the extensive efforts we've undertaken, the profound impacts we've generated, the significant milestones

Evaluating the Impact of Astronomy Programmes for Education, Outreach and Development

Dr Sophie Bartlett

IAU Office of Astronomy for Education. Cardiff University

Abstract

There is a myriad of initiatives in the field of astronomy that are promoting astronomy, outreach, and development across the world, however, the impact of such projects often remains largely anecdotal or is based on limited feedback data from audiences and stakeholders. To further the field, we must work towards systematically evaluating the outcomes and impacts of such initiatives to allow us to work more efficiently and direct our efforts in a focused and effective manner.

This poster presentation will provide a visual guide to developing an evaluation framework for initiatives in astronomy education, outreach, and development. It will provide a step-by-step overview of the importance of evaluation, the process of setting meaningful objectives that will aid practitioners in capturing relevant evidence from which meaningful inferences can be made; creating a logic model or theory of change to identify the context surrounding an initiative, the resources that feed into it, the outputs that will be produced, and the expected outcomes and impacts of the initiative. The presentation will also detail the importance of identifying who is best placed to provide data and feedback in relation to an initiative and when is the best time to capture this. There will also be a summary of different tools and techniques for collecting evaluation data.

Asserting Achievements in Astronomy in Tanzania

Dr Noorali Jiwaji, Dr Said Ally

Open University of Tanzania

Abstract

Though there has been concern about professional level achievements in Astronomy in Tanzania we present clear gains through decades of persistent effort through many ways and methods and challenges. Among the achievements that present is increasing of public interest thousandfold, through articles in English and Kiswahili language articles about novel and exciting Astronomy phenomena and events and using major astronomical events such as the International Year of Astronomy, IYA 2009, and Annular eclipse of 2016 to increase public attention thousandfold across schools, students and public to want to know more about the sky. Particular focus has been given to creating Kiswahili lexicon for basic 3,000 space related terminologies. Another area is in in-service teacher training in Astronomy through the IAU Commission 46 NASE program that encourages hands on activities using locally available materials and creating training through training of tutors. A project to build simple telescopes locally using local material has been effective. An economic impact for the nations is expected from Astrotourism development with dark conducive skies in serene vast national reserves. An Astrotourgouides training curriculum is also in the offing. In research we have achieved Masters level training in Astrophysics with supervision by international experts with local co-supervision for research. Further research is not ongoing for international collaboration in Radioastronomy and a study of science readiness of the Kilimanjaro Saddle area for telescope installation is being undertaken

Survivors Guide to New Media: Engaging Audiences with Bite-Sized Science

Avivah Yamani[1,2], Dr. Pamela L. Gay[2]

[1]langitselatan. [2]Planetary Science Institute

Abstract

The way people look and grab information has shifted. They no longer have time and ability to focus on in-depth science content, but have shifted to content in short, digestible formats.

Short-form video content has easily captivated younger audiences and this bite-sized content has become their resource of choice for information. With content designed to be addictive and easily consumable, users will find themselves scrolling content endlessly. It can not be denied that compressing scientific concepts into engaging, bite-sized content allows the audience to grasp key points quickly and efficiently, without feeling overwhelmed by lengthy explanations.

And here is where communicators should step in and adopt the platform so we can engage with younger demographics. By doing so we are not only providing bite-sized information but also building our brand as a trustworthy resource in Astronomy.

However, simply creating short videos is not enough. To effectively utilize these platforms for science communication, we will explore how to build a trustworthy brand by utilizing short-form video.

Astronomy's role in shaping trade and culture in Bushehr province

Parham Eisvandi Dehnoei

Mehr observatory of Bushehr, Iran. Associate of Inter-Commission C1-C2-C3-C4 WG Astronomy in Culture (WGAC). Associate of Commission C1 WG Astronomy Education Research & Methods

Abstract

For thousands of years, Bushehr Province has been a lively trading hub along the coast, connecting with faraway places like India and East Africa. People here didn't just trade goods; they shared stories, ideas, and knowledge. Astronomy became a common interest, bringing people together across cultures. With similar skies and landscapes, Bushehr became a meeting point for sailors, and farmers alike. This shared fascination with the stars led to new discoveries in shipbuilding, navigation, and agriculture, enriching both trade and culture. In Bushehr, the legacy of this cosmic exchange is felt in everyday life, reminding us of the enduring bonds forged through curiosity and mutual learning.

Bringing Cosmos to Classroom: Astronomy Outreach Practice in Pakistan

Ms Yumna Majeed

Exploration - Cosmos to Pakistan

Abstract

In Pakistan's Space sector, a lack of awareness was observed in educational institutions and among the public, *from* outdated curricula in schools that made science uninteresting for students to the militarization of space agencies that led to no jobs in the country's space sector. Furthermore, there were no public observatories, planetariums or science museums to visit, nor role models or space-career counselling centres where students could progress their professional space careers.

In 2016, a space outreach campaign was initiated which turned into an organisation two years later. *Exploration* was created as a volunteer-run organisation with Ms Yumna Majeed as an Ambassador/NOC for global space NGO's. The mission was to raise awareness about Astronomy among Pakistan's public and promote Astronomy as a subject and career among students. The target audience was narrowed down to primary and secondary schools.

Since Astronomy is an observational science, using art mediums to engage students in themed activities proved to be a useful technique. Teaching methods included presentation-based STEM lectures, observation sessions via telescope, hands-on activities, space-art and storytelling sessions. To build sustainability and keep the outreach inclusive and diverse, private schools were charged to cover the material cost, subsequent funding enabling the same sessions to be conducted at low-income schools, trusts and orphanages for free.

Currently, there's high demand for space workshops, and *Exploration* reached over 110 schools and more than 14,0000 children. Schools started to celebrate World Space Week, universities initiated Space Clubs and authorities and the national space agency started to address space as part of the course curriculum.

A Multilingual Q&A Platform for Demystifying Apophis: A Collaborative World Wide Effort

Mrs. Luisa Fernanda Zambrano-Marin[1,2], Dr. Sean E Marshall[1], Dr. Julie Brisset[1], Mr. Robert J. Christian[3], Dr. Mike Nolan[4], Dr. Ellen Howell[4], Dr. Flavianne Venditi[1], Mrs Gina Morales[5]

[1]Florida Space Institute (University of Central Florida). [2]Universidad de Granada, Escuela Internacional de Posgrado. [3]DRM3 Labs Corp. [4]Lunar and Planetary Laboratory, University of Arizona. [5]Puerto Rico Space Foundation

Abstract

We are developing an online platform called "Ask About Apophis"; this web-based initiative aims to empower the global public with accurate and accessible knowledge about near-Earth object (NEO) Apophis, which will make its close approach to Earth in 2029. The Florida Space Institute, in collaboration with industry leaders in data management, is launching this initiative seeking not only to address public concerns regarding the absence of an impact threat but also to foster international collaboration and scientific understanding.

This platform goes beyond simply disseminating information; it aspires to become a trusted repository for the media to invoke and utilize as a source for accurate information. In today's world of AI-generated content, fidelity of data is imperative, and "Ask About Apophis" aims to establish itself as a reliable source for Apophis related information.

The heart of this program lies in a user-friendly platform specifically designed for multilingual Q&A. By harnessing the collective knowledge of citizen scientists and scientific experts, we aim to create a comprehensive understanding of Apophis and its upcoming encounter with Earth.

We are actively seeking input from the international community in two crucial ways. We invite astronomers and educators to volunteer their expertise.

By providing answers within their field of knowledge, they will directly contribute to public understanding and global collaboration in demystifying Apophis. We seek citizen scientists to submit questions about Apophis through the platform and embark on a collaborative journey of discovery, one question at a time.

An earth and beyond journey : reflections from supporting teacher development and support workshops in South Africa

MR Sivuyile Manxoyi

SAAO

Abstract

The South African National curriculum requires natural science teachers to each astronomy , geology and space science based content organized in a theme called Earth and Beyond and teachers are also encouraged to teach physics and mathematics using astronomy a a context. One of the challenges is that a majority of the teachers are usually uncomfortable teaching this section due to lack of training or exposure . The South African Astronomical Observatory has been facilitating teacher development and support workshops in collaboration with the provincial departments of education, science centres and universities . This presentation will evaluate the interventions implemented , detail the challenges and lessons and recommend best practices to handle and clarify the various misconceptions.

Cosmovisions of the Pacific: Advancing Indigenous - non-Indigenous Collaboration with Integrity (Cosmovisions)

Sr. STEM Education Specialist Yasmin Catricheo[1], Staff Associate for Facilities Planning and Management Tim Spuck[2]

[1]Associated Universities Inc. (AUI). [2]U.S. National Science Foundation

Abstract

Cosmovisions will be a gathering of approximately 100 Indigenous knowledge holders and non-Indigenous researchers and educators in STEM from the Pacific and Pacific Rim nations, and others from around the world who will continue and expand the work initiated by the Cosmovisions of the Pacific Phase 1 Gathering that took place in January 13 - 15, 2023, at the Northwest Indian College in Bellingham, WA, at the Lummi Nation. During phase 1, 30 Indigenous knowledge holders and non-Indigenous researchers and educators in STEM from the Pacific and Pacific Rim nations came together to walk the middle ground together, building new knowledge and relationships across cultures and sharing different ways of knowing our universe. Cosmovisions will create a safe space where individuals can comfortably share what is shareable, carry on and enrich the Cosmovisions of the Pacific report from Phase 1 that identifies key areas of future collaborative research between indigenous and non-indigenous investigators and practitioners. The objectives for of the proposed gathering are to expand and strength the previous exploratory work done by Cosmovisions of the Pacific Phase 1, but are not limited to: Establish a network of Indigenous and non-Indigenous researchers, educators, knowledge holders and others who are committed to collaboration across cultures and ways of knowing, Identify opportunities, in particular in high-need areas, for Indigenous - non-Indigenous Collaboration, Develop a guide for successful Indigenous and non-Indigenous collaboration. This presentation will detail the activities of Cosmovision to date and share information on the upcoming Cosmovisions phase 2.

Mobile Planetarium as a Tool for Astronomy Education in Namibia

Ms Hélène Honsbein[1], Prof. Michael Backes[2], Mr Zandré Duvenhage[3], Mr Hans-Werner Matthaei[3], Ms Queen Delight Namene[2], Mr Lott Frans[2], Mr Francisco Macucule[4], Mrs Sigrid Shilunga[2], Mrs Amanda Schut[3], Prof. Marc Klein Wolt[3], Ms Maaike Pierik[3], Prof. Joanna Holt[5], Mr Hiiko Katjaita[2], Ms Emilia Iiyambo[2], Ms Namasiku Simasiku[2], Ms Victoria Nakafingo[6], Dr. Eli Kasai[2], Prof. Heino Falcke[3], Prof. Sera Markoff[7], Prof. Rob Fender[8], Prof. Elina Lindfors[9], Prof. James Chibueze[4]

[1]University of Vienna. [2]University of Namibia. [3]Radboud University. [4]University of South Africa. [5]Netherlands Research School for Astronomy. [6]University of Stellenbosch. [7]University of Amsterdam. [8]University of Oxford. [9]University of Turku

Abstract

The Africa Millimetre Telescope (AMT) program successfully facilitates a mobile planetarium in Namibia as part of its educational and outreach projects. The idea for the project arose in the early stages of exploring the possibility of building the telescope in Namibia. However, the lack of locally qualified and experienced technical and scientific personnel to run the operations phase became evident as a risk to the sustainable exploitation of the telescope. The mobile planetarium enables us to simultaneously teach and reach out to local talent with an eye towards the future of AMT.

To that end, we adapted an existing mobile planetarium project, run by the Netherlands Research School for Astronomy (NOVA). A unique opportunity arose to set up a sister project in Namibia. Since 2022, more than 12,500 people, mostly schoolchildren, have visited the mobile planetarium. The innovative approach to astronomy outreach - and possibilities for educational purposes - recognized by the Royal Astronomical Society with the 2024 Annie Maunder Medal for Outreach. The IAU Office for Astronomy Education provided seed funding to create training material for student presenters. The project is now gaining such traction in Namibian society that many local businesses support the team with financial or in-kind support.

This contribution explores the best practices of a mobile planetarium for astronomy education, showcases differences and similarities in running this project in the Netherlands and Namibia, and explores the reasons why the feeling of ownership of the project in Namibia is so strong.

Teaching astronomy to students through Heritage and Archeoastronomy of Iran and the world

Director of Mehr Observatory Maryam Papari[1,2,3,4,5], Fatemeh Salimi[6,7], Coordinator of Mehr Observatory Anahita Zadsar[8], Researcher Hossein Khezri[9]

[1]Director of Mehr Observatory/ Ministry of Education, Iran. [2]Associate of Commission C1 WG Astronomy Education Research & Methods. [3]Associate of commission C1-C2-C3-C4 WG Astronomy in Culture (WGAC). [4]NAEC of Iran. [5]LOC of NASE (network for astronomy schools education) in Iran. [6]Biology teacher. [7]Deputy director of Khormuj research institute/ministry of education, Iran. [8]Coordinator of Mehr Observatory. [9]Researcher

Abstract

Students' familiarity with astronomy can be started in different ways, and one of these ways is to teach students about Heritage and Archeoastronomy. Mehr Observatory, as a center under the supervision of the Ministry of Education of Iran, has started the project of teaching heritage and archeoastronomy to Iranian students. In this way, schools officials, families and teachers, also accompany the students in the process of learning. In this presentation, we will explain the programs, workshops held, observations in astronomical sites that have a history of thousands of years, and also about the formation of groups of teachers and students in different cities of Iran with the aim of promoting and teaching astronomy to students.

Fostering STEM Interest through Practical Astronomy Education: The Astronomy in Ghana Project

Mr Joshua Kalognia[1], Mr Albert Forson[2], Miss Sarah Abotsi-Masters[2], Dr Emmanuel Prven-Adzri[3], Dr Naomi Asabre Frimpong[3], Miss Christiana Adorkor Kpakpo[2], Mr Stephen Ofoe Sottie[2]

[1]PRAGSAC/University of Cape Coast. [2]PRAGSAC. [3]GSSTI/PRAGSAC

Abstract

The Astronomy in Ghana project has successfully pioneered practical astronomy education in six schools across three southern regions of Ghana. With a focus on promoting problem-solving skills and cultivating STEM interest, the initiative began with a comprehensive 2-day preparation workshop, meticulously crafting an astronomy curriculum and teaching materials.

Emphasizing the significance of astronomy, the team conducted school visits, encouraging active participation in newly formed astronomy clubs among both students and teachers. To ensure long-term sustainability, a dedicated 2-day patrons' workshop equipped club leaders with the necessary knowledge and skills, complemented by a Teacher Training handout containing astronomy topics and activity materials.

Club progress was monitored through evaluation sessions, featuring pre and post astronomy questions to gauge students' understanding. Results indicated a significant enhancement in students' knowledge of various astronomy subjects. Enriching the educational experience, astronomy clubs visited the Ghana Radio Astronomy Observatory, gaining practical insights into a 32 m radio telescope and its operation.

The project concluded with an inter-school astronomy quiz competition, showcasing the acquired knowledge, with St. Martha’s Catholic Basic “B” School emerging as the winners. Overall, the Astronomy in Ghana project has effectively introduced practical astronomy topics, hands-on activities, and astronomy clubs to Ghanaian schools, significantly enhancing STEM interest and playing a pivotal role in guiding informed academic and career choices.

Engaging Minds, Empowering Action: Interactive Learning Materials for Effective Science Outreach

Mr. Lealem Kinfe

Ethiopian Space Science Society

Abstract

"Engaging Minds, Empowering Action" recounts a journey of impactful science outreach, where innovative learning materials become catalysts for change. Drawing from my background in computer engineering and a deep commitment to bridging educational divides, I've crafted interactive tools – flyers, brochures, digital posters, PDFs, engaging question cards about space science, and stickers – tailored for outreach programs in regions with limited educational resources.

The materials transcend traditional barriers, transforming complex astronomical concepts into digestible, visual narratives. Through interactive sessions, I witnessed students in the countryside grasp even the simplest astronomy principles, sparking a newfound fascination for the cosmos.

In the war-affected northern part of Ethiopia, the power of stickers as a reward system became evident. By distributing stickers to students answering questions, we not only encouraged active participation but also offered a momentary escape from the challenges they faced. These tangible rewards transcended the realm of education, providing a source of joy and motivation in the midst of adversity.

This abstract encapsulates not just a commitment to education but a narrative of empowerment and resilience. The proposed materials aim to kindle curiosity, making science an accessible and enjoyable journey for students in challenging circumstances. This story-driven approach underscores the transformative impact of tailored learning tools, turning outreach programs into beacons of hope and inspiration. I look forward to sharing these experiences, offering a glimpse into the profound change that science outreach can bring to underprivileged communities.

Empowering Through Astronomy: Girls in the Museum of Astronomy

Dr. Patricia F Spinelli[1], Dr Alejandra Irina Eismann[1], Claudia Sá Rego Matos[2]

[1]Museum of Astronomu and Related Sciences. [2]Observatorio Nacional

Abstract

The goal of science outreach is to diminish barriers between the academic realm and society, making scientific knowledge more accessible to diverse audiences. However, when it comes to informal education activities, experts recognize that it can be more expansive than mere dissemination: knowledge should be used to empower individuals and transform society.

The third edition of the project “Girls in the Museum of Astronomy” promoted activities to 35 girls aged 11-15, residents of Rio de Janeiro’s favelas. The project’s primary objective was to encourage these girls to experience science in the context of school clubs.

To achieve our goal and considering the harsh societal context of the participants, we have strived to move beyond the conventional approach of exclusively sharing astronomy content. This departure was also motivated by the mission of the project's hosting institution, a museum, where history and heritage must not be overlooked.

In this talk, we will present how astronomy activities can be conducted broadly and tailored to the interests of the audience while addressing cultural, philosophical, aesthetic, creative, and emotional dimensions. Specifically, we will showcase examples around the theme ‘Light Pollution’ explored by project's participants in various ways. Their findings were presented at prestigious events, transforming into astronomy ambassadors, earning awards in Olympiads and state fairs. However, the most significant outcomes are immeasurable — a noticeable shift in the girls' attitudes towards science and in their communities, manifested in various meaningful ways

Mandate of Heaven: an epistemological study on the astronomical thought in Ancient China

Mx Jun Nakayama

Federal University of Rio de Janeiro

Abstract

The history of astronomical advancements has always been told from an European viewpoint, using Western rulers to measure the quality and merit of discoveries. However, History of Science can't be separated from decolonial discussions and isn't exempt from bias. While the timeline for the evolution of the cosmological perspective was drawn from Western sources, from Ionians to Galileo, other ways of interpreting the sky were being developed independently from these European influences and those aren't unworthy of mention. The study of the Heavens was a science of cardinal importance for ancient Chinese society, with an almost symbiotic relationship between Man and the Cosmos. Despite its uniqueness and remarkable advances made by early astronomers, the Western narrative usually paints ancient Chinese astronomical knowledge as primitive, underdeveloped and poor in theory, but it's not possible to study completely different civilisations using the same cultural lenses. The aim of this work is to showcase the characteristics of astronomical thought in Ancient China between the Zhou and the Han dynasties (1045 BCE - 220 ACE), in an attempt to distance it from the Western context's bias, emphasising how the social and cultural connection to the Heavens in this period contributed to significant developments in Astronomy.

Heritage and Culture as Tools for Teaching Astronomy

Prof Somaya Saad, Miss Ola Ali

National Research Institute of Astronomy and Geophysics, NRIAG

Abstract

The Astronomical heritage is an integral part of the global human cultural heritage, and extends deep into the human conscience. Ancient man in all civilizations was interested in observing the sky and the stars shining in the sky and recording their sunrise and sunset. The sun and its movement in the sky during the day meant a lot to humans. In addition to spreading warm light that represented safety and renewal of daily life, it helped determine time and days.

Time was recognized and divided into parts as years, months, days, and hours. This has been a huge part of the work and ongoing efforts. Whereas, in more advanced stages, man made tools to help him calculate time, such as the hourglass and the water clock, and used the sun's shadow, which lengthens and shortens during the day, to tell the time.

With the knowledge of writing, man began to write down and record these notes in lists, maps, and manuscripts, which represent a great wealth and heritage accumulated over time.

Here we will review the Egyptian astronomical heritage, which was built on scientific foundations and precise knowledge of astronomy, and we will use these concepts as a good and effective means to teach students many astronomical lessons in an interactive and tangible way. We will focus on how astronomical heritage can be used as an ideal tool for teaching astronomy, and will orient pupils and the public to the importance of preserving their history and culture through astronomy education.

Human Capital Development and Research Capacity Building for the MeerKAT and SKA projects.

Dr Mthuthuzeli Zamxaka

South African Radio Astronomy Observatory (SARAO)

Abstract

The South African Radio Astronomy's human capital development programme (SARAO-HCD) was established to ensure that a sustainable and demographically representative workforce of highly skilled engineers, scientists, technicians and artisans would be available to build, operate and use the SKA, MeerKAT and AVN radio telescope facilities, as well as other local radio astronomy experiments.

Since its inception in 2005, SARAO HCD has successfully grown – from a very small pool - a diverse, interactive, globally recognised and transformed radio astronomy community in South Africa. This community participates and exploits the scientific and technical research opportunities that have been made available through South Africa's strategic investments in radio astronomy, particularly the MeerKAT and SKA projects, and thereby continues to secure the country's return on its investment. It has enabled the growth of SARAO's social license to operate with local communities, and is a critical success factor in ensuring the long-term strategic objectives for radio astronomy investment in South Africa is attained.

When South Africa submitted its expression of interest to host the SKA in 2003, there were less than five radio astronomers in South Africa. Since then, over 1400 grants to postdoctoral fellows, postgraduate and undergraduate students doing science and engineering degrees and research at universities, and universities of technology, and students training to be artisans, have been awarded by SARAO - a significant return on South Africa's investment in the international SKA effort, and the construction and operation of MeerKAT.

ASTRO ACCEL for Advancing Astronomy Education, Development, and Cultural Understanding

Tiffany Stone Wolbrecht[1], Kelly Blumenthal[2], Nic Bonne[3], Yasmin Catricheo[1], Anica Miller-Rushing[1], Saeed Salimpour[4], Tim Spuck[5], Gretchen Stahlman[6]

[1]Associated Universities, Inc. [2]IAU Office for Astronomy for Outreach. [3]Univeristy of Portsmouth. [4]IAU Office for Astronomy for Education. [5]U.S. National Science Foundation. [6]Florida State University

Abstract

Learn more about the ASTRO ACCEL initiative, a global collaborative effort dedicated to promoting research and leveraging expertise in astronomy education for development and cultural enrichment. Comprising 13 interconnected networks, including prominent contributions from the International Astronomical Union (IAU), ASTRO ACCEL spans continents to accelerate the exchange of resources, ideas, and practices in culture, communications, education, and public engagement within the realm of astronomy. By uniting researchers and practitioners and supporting early career researchers, ASTRO ACCEL aims to cultivate a vibrant community where collaborative priorities are established, innovative strategies are shared, and significant strides are taken toward enhancing astronomy education and fostering cross-cultural understanding.

Armenian Activities on Astronomy-related Inter- and Multi- Disciplinary Studies

Gayane Baleyan, Areg Mickaelian

Byurakan Astrophysical Observatory

Abstract

All sciences in the world, especially the natural ones, move toward each other creating both Interdisciplinary (ID) and Multidisciplinary (MD) fields. Astronomy is probably the leader in this tendency, as data coming from the Space serve for and develop many natural and also social sciences: The Byurakan Astrophysical Observatory (BAO) and later on, the IAU South West and Central Asian Regional Office of Astronomy for Development (SWCA ROAD) have been very active in promoting such fields. In 2012, an Archaeo-astronomical Conference *"Astronomical Heritage in the National Culture"* was organized in Byurakan. Then one of the first meetings on Astronomy as the leader in ID and MD sciences was held, *"Relation of Astronomy to other Sciences, Culture and Society"* (RASCS, 2014) and a similar meeting *"Astronomy in the Crossroads of Interdisciplinary and Multidisciplinary Sciences"* was held in 2021. In addition, one of our Byurakan International Summer Schools (BISS) had a title *"Astronomy as the leader of Natural Sciences"* (2022). As in 2014, RASCS topic will have the Armenian Astronomical Society (ArAS) 25th anniversary meeting in 2024. The most prominent meeting was probably the UNESCO Regional Conference in 2017 on *"Astronomical Heritage of the Middle East"*. BAO actively collaborates with related international organizations: International Virtual Observatory Alliance (IVOA; VOs, Astroinformatics), International Planetary Data Alliance (IPDA; Planetology), ISC World Data System (WDS; Data Science), COmmittee on SPAace Research (COSPAR; Space Sciences and Technologies), IAU Working Group on Archaeoastronomy and Astronomy in Culture (WGAAC), European Society for Astronomy in Culture (SEAC) and others.

Astronomy Outreach in Nigerian High Schools

Ms Barivure Popnwin

North-West University

Abstract

Astronomy, as a field of scientific inquiry, stands as a beacon of exploration. Throughout history, astronomy has not only deepened our comprehension of cosmic phenomena but also provided profound insights into our place in the cosmos. In Nigeria, the accessibility of astronomy and space science remains a challenge. The absence of educational institutions offering space science curriculum poses a significant barrier to students' exposure to astronomy, a scarcity extending across the nation with only a handful of universities offering astronomy programs. Despite these challenges, I seized opportunities to engage with high school students during my one-year community service in Nigeria. Through presentations at schools like The Nigerian Air Force High School in Akwa Ibom State and Premiere Academy in Lugbe, Abuja, I endeavoured to instill a sense of curiosity about space science and astronomy among young learners. Witnessing their enthusiasm reaffirmed the belief in the crucial role of Astronomy outreach in bridging educational disparities, while the road to advancing astronomy education in Nigeria may be fraught with challenges, the potential impact on inspiring future generations of scientists makes it a journey worth undertaking. Through concerted efforts in outreach and education, we can cultivate a new generation of astronomers who will contribute to the global pursuit of knowledge about the universe.

Advancing Astronomy Education: Innovative Outreach Projects to Inspire Future Astronomers

Gayane Baleyan

Byurakan Astrophysical Observatory

Abstract

In the pursuit of fostering a deeper understanding and appreciation for the cosmos, the Byurakan Astrophysical Observatory (BAO) has been at the forefront of organizing diverse Outreach and Educational events. As we prepare to engage with esteemed colleagues at the International Astronomical Union General Assembly, we present a comprehensive talk outlining our vision and initiatives aimed at advancing astronomy education and cultivating a passion for the celestial sciences.

At BAO, we recognize that effective astronomy education transcends traditional classroom settings and necessitates innovative outreach strategies that captivate the imagination of learners of all ages and backgrounds. Our educational projects are designed not only to disseminate astronomical knowledge but also to instill a sense of wonder and curiosity about the universe.

Key components of our outreach initiatives include:

- **Public Stargazing Events**: Leveraging our state-of-the-art telescopes, we organize regular stargazing sessions open to the public.
- **Virtual Astronomy Workshops:** Through interactive sessions, we cover a range of topics, from basic astronomical concepts to cutting-edge research developments, fostering a global community of astronomy enthusiasts.
- **School Outreach Programs:** We collaborate with local schools to develop tailored astronomy curriculum supplements and conduct engaging workshops and demonstrations on-site.
- **Citizen Science Initiatives**: We involve enthusiasts in data collection and analysis projects. By democratizing the scientific process, we not only advance our understanding of the cosmos but also foster a sense of ownership and pride among participants.
- **Art and Astronomy Fusion Events**: We organize events that explore the intersection of astronomy and various art forms.

Evaluating Astronomy Education in Uganda and Africa through Vlogging

MR. TERRY MARK TUKAMUSABA

KYAMBOGO UNIVERSITY,UGANDA

Abstract

Abstract:

This proposal outlines a pioneering initiative aimed at transforming astronomy education in Uganda and across Africa through the innovative use of vlogging. Recognizing the importance of accessible and engaging educational content, this project seeks to leverage the popularity of online video platforms to inspire a new generation of astronomers, foster scientific curiosity, and bridge the cosmic gap that often exists in regions with limited access to traditional educational resources.

The primary objective of this project is to create a dynamic ,scientific and culturally relevant vlogging series that delivers astronomy content in an engaging and accessible manner. The aim is to demystify Astronomy by developing content that simplifies complex astronomical concepts, making them accessible to a wide audience with varying levels of scientific background, integrating local cultures, folk tales, and indigenous knowledge into astronomy lessons, fostering a sense of connection between the cosmic realm (particularly stellar pulsations in low mass stars initially) and everyday life. Promoting diversity while showcasing diverse role models and professionals in astronomy, emphasizing inclusivity and encouraging underrepresented groups, particularly women, to pursue careers in STEM fields is also essential alongside community engagement to establish a feedback loop through online platforms, encouraging audience participation, and tailoring content to address specific questions and interests of the viewers in the various areas separated by language differences.

The project will employ content creation ,platform utilization and community Outreach.

The development of astronomy public-outreach activities in Bratislava in Slovakia

Doctor Patrik Čechvala[1], Doctor Juraj Kubica[2]

[1]Comenius University in Bratislava, Slovakia. [2]Slovak planetaria, residents association

Abstract

Although, Bratislava, capital of Slovakia, is the agglomeration with more than half of million of inhabitants and the place where the biggest slovak university is located, we have been struggling with the support and the development astronomy-related outreach activities in this region for several years. This was most visible when Park of Culture and Relaxation was closed also with its Astronomy office around 20 years ago. Since then, Bratislava is missing any type of official public-outreach institution for astronomy. However, there are nowadays several activities to change this status. There is an initiative to build a planetarium after long decades of waiting. Also the new observatory is currently being built at the high school in Bratislava. We would like to briefly summarize different current astronomy-related outreach acitivities in our capital city.

Digital Astronomy Festivals - Bridging Enthusiast Communities and the General Public. An Analysis of Results and Challenges

Pr Andres David Torres Cañas[1,2], Dr Camilo Delgado-Correal[3,4,5], Mag Carlos Molina[6,7]

[1]Metropolitan Technological Institute (Medellín - Colombia). [2]NOC Outreach Astronomy Office (Colombia). [3]Francisco José de Caldas District University of (Bogotá-Colombia). [4]Geographic Institute Agustín Codazzi - IGAC (Colombia). [5]ViceNOC Outreach Astronomy Office (Colombia). [6]Planetarium of Bogotá (Colombia). [7]Inmerdome S.A.S

Abstract

In 2020, during the quarantine prompted by the covid-19 pandemic, the Office for the Outreach of Astronomy of the International Astronomical Union in Colombia (IAU-OAO Colombia) proposed a strategy to maintain the connection between the community of enthusiasts and the general public interested in astronomy: the creation of a Digital Astronomy Festival (AstroFest) . In these event, astronomy groups offered lectures, workshops, panels, and discussions on topics previously defined by the OAO's expert committee. The festival took place for one day, usually during the September equinox week, and has already had three editions, each per year. In the third festival, more than 200 people participated by connecting to the Zoom platform, and additional viewers tuned in for the 12-hour live broadcast on the OAO's YouTube channel. This work aims to present the results obtained in all editions of the festivals and explore the possibility of expanding this format to other regions of the world and by using other platforms like Tik Tok and Virtual Reality environments.

The Sun at a Glance: An International Infographic Competition to Teach Science at School

Luis Bellot rubio[1], Mariarita Murabito[2]

[1]Instituto de Astrofisica de Andalucia (IAA-CSIC). [2]INAF-Osservatorio Astronomico di Capodimonte

Abstract

Innovative activities are needed to promote STEM vocations among young students. The Sun, as an object that can be studied from many different perspectives, offers an excellent opportunity to accomplish this goal. In 2021, the European Solar Telescope (EST) project organized the international competition “The Sun at a glance” to show the potential of the Sun for teaching science at school. Here we describe the philosophy, the main organizational aspects, and the results of this activity.

The competition was designed to encourage students in the age ranges 14-15 and 15-16 to research about the Sun and present their results in the form of an infographic. The students worked in small teams of 4 people, led by a teacher. The prizes included a visit to Teide Observatory (Tenerife, Spain) for the two teams producing the best designs. A dedicated website (www.est-east.eu/contest) was set up to provide the participants with the rules, the announcement poster, and other general information. The names of all the students and their teachers were also listed on the website in real time.

This activity raised extraordinary interest in the European education community. A total of 2,859 students and 303 teachers from 242 schools signed up for the competition, representing 16 European countries. The infographics they submitted were used to build the EST Solarpedia, a comprehensive solar encyclopedia hosted on the EST website. This unique educational resource, open to both the teaching community and the general public, is a legacy that will stand for years to come.

CHASING THE STARS NAKED EYE The Benin Tofin fishermen challenging modern telescopes in daily navigation

Prudence AYIVI[1], Dr Aimé SEGLA[2], Jean-Eudes MISSIKEY[2]

[1]Sirius Astro-Club. [2]University of Abomey-Calavi

Abstract

Where do Indigenous knowledge holders and their astronomical knowledge sit in the modern techno scientific future of astrophysics? The present project revolves around the research among the indigenous peoples of the Tofin, a West African people living mainly in southern Benin, Nigeria, Togo and Ghana and attempts to address the question. Our methodology consists on collecting, using the Tofin local language, concepts in links with astronomy. It is indeed scientifically interesting to find out how, for example, the local sky knowledge influences the culture and the local knowledge of procedural boat building technologies. It appears during our fields work those meanings are aligned on the knowledge of the stars. Furthermore, we seek to document the knowledge of the sky as guidance in daily navigation for fishing on the sea, lake and lagoons, as basis for the organization of social and cultural life, and for more: the cycle of the stars is used to define the harvest periods; stars are used as guides during extensive marine navigation, etc. During on-site expeditions, we organize evening observations with modern telescopes to verify the accuracy of peoples' empirical knowledge with modern theoretical models, thus allowing local people to better connect with future technological innovations. In conclusion, the Tofin fishermen propositions to the Benin Government, based on their secular experiences, are substantial for the improvement of fishing economy and for the development of the urban coastal areas in southern Benin Republic.

Key words: Astrophysics; indigenous-knowledge; Tofin (Benin); cultural astronomy; innovation-studies.

AstroSounds - Listen to the Stars

Professor Katrien Kolenberg

KU Leuven. University of Antwerp. Free University of Brussels

Abstract

Our Universe is full of sound. In the depths of space, planets of all flavors crackle and roar, stars are ringing like giant bells, and merging black holes occasionally send ripples through the fabric of spacetime. And this is just the tip of the cosmic iceberg…

Within the vast field of Astrophysics, the study of variable stars is expansive and inclusive. Groundbreaking discoveries can be made with modest instrumentation and small telescopes, also by amateurs, and treasure troves of new unexplored data are available to the scientific community and the public. Therefore, this field lends itself perfectly to involving more people in astronomical research, sharing a cosmic perspective on our human scientific endeavors, and using it as a "hook" for STEAM education.

AstroSounds is a citizen science project investigating the extent to which the human ear can distinguish the timbre of different pulsating star types. At the same time, it is an educational project, inspired by the research field of asteroseismology, naturally linking different STEAM curriculum topics, such as physics, mathematics, biology, chemistry and music education. The multimodal exploration of data, including the auditory channel, opens the field of astronomy to people with visual impairments.

Astronomical education in the Democratic Republic of Congo, a challenge for primary and secondary education

Professor Nsiami Catherine Mabiala

Coordination pour l'éducation astronomique en RDCongo

Abstract

Education in general, and astronomical education in particular, is a major challenge for the Democratic Republic of Congo, in a context of war and poverty. Priorities are often clear, but they are far from astronomical. This challenge becomes that of national coordination, which relies on the few amateur astronomers and on the advice of the only professional Congolese astronomer living outside the country. The main question is how to give astronomy a face so that it attracts the attention of primary and secondary school-age children? The awareness-raising activities organised with the means at hand seem to be bearing fruit, but they are insignificant given the size of the country. This paper takes stock of what is being done and presents the vision of the national coordination for astronomy education in the DRC.

Ingredients for New Discoveries: Sun, Solar Eclipse, Earth's Atmosphere, and the Local Community.

Dr Juie Shetye

New Mexico State University

Abstract

The annular solar eclipse of October 14, 2023, catalysed collaborative research efforts between academic institutions, a barn, and over 200 local enthusiasts. Through partnerships with NASA, Montana State University, and the New Mexico Space Grant Consortium, the project aimed to investigate the atmospheric impacts of the eclipse. Methodologies involved deploying high-altitude balloons equipped with radiosondes to collect essential atmospheric data.

These experiments discovered over 30 eclipse-driven atmospheric gravity waves, observed for the first time during an annular solar eclipse.

The icing on the cake was the public photographs that captured the formation of these waves in clouds created at the locations, thus providing a unique means to make scientific discoveries and visually confirm our results.

The presentation underscores the significance of experiencing totality in a specific location and highlights the broader impact of the eclipse on both scientific understanding and public engagement with astronomy.

Abstract

In this talk we describe our experiences through travels to several towns and cities in whose libraries, cultural centers and even main squares where developed activities concerning Astronomy, Cultural Astronomy and care of dark skyes; each one of this journeys had a diverse way to be concreted, we review from these wich will be the best way to perform a succesful activity, we introduced there organizations such *Network for Astronomy School Education* and their different courses for teachers, as well activities from popularization and outreach area from *Instituto de Astronomía y Meteorología* at *Universidad de Guadalajara* as a form to develop consciousness of their Astronomical Heritage and the preservation of dark skyes.

Junior Astroclub - An educational project for interactive teaching of astronomy.

Simon Anghel[1,2], Diana Chirita[3], Andra Stoica[3]

[1]Astronomical Institute of the Romanian Academy. [2]IMCCE - Paris Observatory. [3]Space Club

Abstract

Astronomy sparks a natural curiosity and passion in many from an early age, making learning feel effortless. Despite its potential to boost critical thinking and scientific reasoning, it's often overlooked in school curriculums. Thus, in 2018, a group of amateur astronomers from Romania initiated the “Junior Astroclub” project, with a dedication to teach astronomy to children from diverse communities through engaging activities.

The club's initiatives include practical and interactive projects like courses, crafting homemade planetariums, comets, space elevators, drawing celestial bodies etc. These activities are designed to be educational yet captivating, ensuring the kids not only learn but also enjoy the process. As the project is not linked with an external funding scheme, we rely on a minor support from the parents, which is invested in teaching materials. This small fee for the online courses also incentivised the parents to ensure that the kids never miss a workshop.

The project was a great success, participants eagerly awaiting future workshops and other activities. Thanks to the online workshops, Romanian children across all Europe could join in, overcoming geographical barriers. The absence of mandatory homework hasn't hindered learning, confirming that the peak of the learning process resides at the intersection of passion and creative educational activities.

The team: A. Stoica, D. Chiriță, S. Anghel, E. Anton, B. Arion, M. Barbu, M. Boicescu, M. Crețu, Ș. Mirică, M. Naiman, A. Neaga, A. Nichiforov, C. Palade, O. Pănoiu, A. Perrota, S. Roșu, A. Soare, M. Sinca, C. Stancu, G. Stratulat, C. Șulea, V. Vasile

'Ale Lau Loa: Indigenous Culture-based Learning

Dr Yuko Kakazu[1,2], Dr Fengchuan Liu[1]

[1]TMT International Observatory. [2]National Astronomical Observatory of Japan

Abstract

The Thirty Meter Telescope (TMT) International Observatory is dedicated to an inclusive community model of astronomy that upholds the values of respect, inclusion, and community stewardship. Under new management and a Hawai'i-based team, TMT actively engages in grassroots dialogues with community members, especially with Native Hawaiians. Through community input, diverse programs in education, workforce development, culture-based learning, and environmental conservation are co-created and community-reviewed.

This presentation introduces the 'Ale Lau Loa: Indigenous Culture Exchange Program, symbolizing the profound and enduring histories of indigenous cultures. Developed in collaboration with the Hawai'i County Sister City program, TMT, and guided by cultural practitioners and wayfinders, this community-driven program fosters cultural exchange between Hawai'i Island high school students and global peers, emphasizing indigenous traditions and their deep connections to the sky and the ocean.

Sky Machines: Manufacturing and prototyping of educational materials on astronomical topics for non-specialized audiences. Cintia Durán. Tlaloque. HackerGarage.

Cintia Duran

Tlaloque. HackerGarage

Abstract

An important problem we share in astronomy outreach is the limited tools we have for establishing common ideas with society. There is a wide range of communication strategies designed without much room for the public to experiment and learn by themselves. All this under guidelines and practices of international models, overlooking the specific needs of each country. This project gives a sample of the work we have done in the city of Guadalajara, Mexico in collaboration with HackerGarage, a citizen technology lab, for the design and prototyping of didactic materials that can be used by the public and responding to the specific challenges of the communities that use them.

Our main focus is the mix of industrial design and other technologies that can be used to complement outreach/education practices while giving the user a sense of participation in the construction of their own devices. Once we select a topic, and the scientific research is well structured, we start to transform that content into a tangible object, that can transmit complex concepts, and meet the needs of the user without an intermediary or prior knowledge of science.

From our experience, in a Latin American country, where social problems exceed academic needs, we saw in industrial design and DIY culture, a powerful, affordable, and inclusive tool, that can be used in the manufacture of educational products and a way to approach complex issues reinforcing a positive relationship with science, positioning it as something familiar in their day to day life.

A sun that never sets. Outreach techniques through language, and the importance of oral tradition in astronomy studies.

Cintia Duran[1], Dr. Kelly Blumenthal[2]

[1]Tlaloque. [2]IAU

Abstract

A sun that never sets proposes a linguistic analysis, whose basis is built on the research of different languages of native communities in four regions of the world, to design astronomy outreach strategies specific to each community. We take as a starting point concepts from the Systematic Functional Grammar studies, where it is established that the structure of language that each society develops dictates roles, behaviors, and ways of learning. All this to explore the relationship that different indigenous cultures have established with the earth and the cosmos, and in consequence modify concepts and practices of astronomy communication that can be used by different communities.

Giving relevance to the language of each community can be a solid tool for the development of a new stage in the relationship that astronomy has with society, creating the foundations for new multidisciplinary research from astronomy for the benefit of humanity.

We start with the importance of **making evident the differences between languages** and forms of communication in each country because by honoring these differences we can understand the history and customs of a people, as well as their way of thinking and expressing themselves. **It is in the recognition of the community that we can modify and add new concepts in the teaching** and communication of scientific topics.

Implementing the Cascade Outreach Model in Astronomy Engagement during national Science Week 2023

Ms Duduzile Kubheka

African Astronomical Society. BRICS Astronomy. South African Astronomical Observatory. Stellenbosch University

Abstract

Our project during National Science Week 2023 in South Africa epitomized a collaborative endeavor aimed at igniting curiosity and nurturing a passion for astronomy, particularly among youth, while also spotlighting potential career paths in STEM fields. Through strategic partnerships with local education departments and the enthusiastic participation of dedicated outreach ambassadors, mainly comprised of astronomy postgraduate students, we extended the initiative's reach across multiple regions in South Africa, covering over six provinces. A pivotal innovation was the introduction of the "cascade outreach" model, inspired by the exemplary work of Carolina Odman, facilitating the dissemination of astronomical knowledge while championing diversity, inclusivity, and leadership in science communication. Targeting learners in townships and remote areas, we broke geographic and socioeconomic barriers, bringing astronomy directly to those with limited exposure. The engagement was both informative and inspirational, fostering interaction with relatable ambassadors and igniting curiosity among participants. Moreover, the project significantly impacted participating ambassadors, equipping them with valuable communication skills and nurturing a sense of social responsibility. This collective action exemplifies the transformative potential of promoting science awareness and capacity-building in African communities, fostering a legacy of scientific curiosity and empowerment.

DIY Radio Telescopes for Education and Outreach in Developing Countries

Dr Ikechukwu Obi, Mr Ike James, Mr Williams Onyinyechi, Dr Bonaventure Okere

Centre for Basic Space Science & Astronomy (CBSS)

Abstract

Outreach and educational activities in astronomy in developing countries have over the years focused on optical astronomy with little or no activities were carried out in the radio counterpart despite it's feasibility of daytime observations which in turn allows for it's easy inclusion in the curriculum activities of schools. This is mainly due to the unavailability of ready-made expensive radio telescopes or lack of expertise to build low cost ones. On the other hand, professional radio telescopes can not be easily accessed by students for teaching purposes due to it's high demand. We present various designs and performances of some affordable but effective mobile and portable DIY radio telescopes that will serve as an indispensable tool for outreach, education and training in radio astronomy at all levels.

Inspiration through space science: exoplanet themed education activities for secondary students

Sandor Kruk[1], Kate Isaak[1], Catia Cardoso[2], Maximilian Guenther[1], Davide Gandolfi[3], Sandra Benitez Herrera[1], Monica Talevi[1], Clara Cruz Niggebrugge[1]

[1]European Space Agency. [2]Aurora Technology B. V. for ESA. [3]University of Turin

Abstract

The topic of exoplanets is connected directly to the simple and profound question of whether we are alone in the Universe, capturing the imagination of scientists and the public alike. As such, it provides an excellent means through which to engage school students in some of the thrills of science and, critically, to teach science, technology, engineering and mathematics (STEM) core skills.

In this contribution we give an overview of a collection of exoplanet inspired classroom activities and resources that have been developed through a collaboration between ESA Education and scientists working in ESA Science and beyond. The emphasis of the activities has been on transit photometry and more specifically ESA's CHEOPS mission, with the underlying theme of using in-flight CHEOPS observations to engage young people. A highlight is the 'Hack an Exoplanet' (https://hackanexoplanet.esa.int/) challenge, in which student teams engage in the analysis of several exoplanets observed by CHEOPS for this educational purpose. Through these initiatives, we demonstrate the power of using real scientific missions' data to inspire the next generation of scientists and engineers, underscoring the critical role of hands-on, practical experiences in STEM education.

Communicating Astronomy: The IDP Experience

Engr Onuche Ogu

AWBNigeria/NASRDA

Abstract

My submission will address a wide range of challenges in communicating astronomy. The IDP-CAO Project target audience is children below the age of 18. The target audience have been through the traumatizing effects of violence and displacements from their homes due to ethno-religious conflicts. The results of cognitive behavioral therapy assessments show that a huge percentage of the target audience suffer from anxiety disorders. The target audience have little to no knowledge of astronomy and science. The target audience have become familiar with folklore and myths concerning the wonders of the sky.

The presentation will address the multifaceted challenge of communicating astronomy to children that have experienced violence and dealing with the effects mentally. Also, the challenge of demystifying common folklore that have become all familiar to the target audience.

Participants will learn the following from my submission:

1. Inter-disciplinary approach to astronomy communication.

2. The use of multimedia in communicating astronomy to children.

3. The importance of gaining trust before embarking on astronomy communication

This project employed interdisciplinary approach to holistically achieve it aims and objectives by using a team of professional counsellors to conduct cognitive behavioral therapy assessments. This approach was done to gain insight on the state of the mental health of the children and to gain their trust. Data from the psycho-social therapy assessments and the impact of the project have been analyzed.

Paths to promote inclusive Astronomy learning environments: from teacher trainings to multisensory resources

Ms. Mariana Gomes

FIOCRUZ. Museum of Astronomy and Related Sciences

Abstract

In the vastness of human knowledge, Astronomy becomes a window for contemplating the Universe, playing a vital role in acknowledging our role as global citizens. That said, the construction of a teaching and learning process of Astronomy concepts demand an exhaustive exercise of optimism. However, outlining educational paths in Astronomy necessitates a careful analysis of challenges faced by both protagonists in the classroom – teachers and students. In this work, an offshoot from the production of multisensory resources to teach about the Moon for visually impaired students at the Universo Acessível project, our discussion underscores the potentials of using multisensory resources inside the classrooms and the emergent need of teacher trainings to instill confidence in teaching Astronomy and effectively leveraging such resources, by showing a panorama from the Astronomy education in Brazil, from a qualitative research study targeting Brazilian teachers in the field of Natural Sciences, where they were asked about realities faced in the Astronomy teaching inside classrooms. We expect to discuss how promoting an inclusive learning environment can engage students and teachers from the beginning and create a good environment for Astronomy teaching and learning, emphasizing the need to spotlight teachers as key players in the Astronomy Education process. Our aim is to explore how fostering an inclusive learning environment can captivate both students and teachers from the outset, establishing a conducive atmosphere for Astronomy education. This discussion reinforces the potential for initiatives that interconnect astronomers, educators, and students collaboratively, guiding the learning process of astronomical concepts while solidifying teacher training in this field.

The Role of the African Astronomical Society in Shaping Astronomy in Africa

Dr Naomi Asabre Frimpong

African Astronomical Society (AfAS)/ Ghana Space Science and Technology Institute (GSSTI)

Abstract

Since its relaunch in 2019, the African Astronomical Society (AfAS) has made notable strides towards contributing to advancing the field of astronomy within Africa, with a focus on education, research, and public engagement. This presentation aims to show AfAS's different initiatives, including comprehensive capacity-building efforts through workshops, astronomy schools, grant programs, and extensive outreach activities that have aimed to increase public access to astronomy. Furthermore, the society's commitment to fostering research and facilitating international collaborations has elevated the global presence of astronomy in Africa. The presentation will also address society's contribution to supporting infrastructural development and policy advocacy, underscoring its dedication to the sustained growth of astronomy across the continent. By reviewing AfAS's accomplishments, challenges faced, and prospective goals, this talk intends to provide a thorough overview of the society's role in enriching the African astronomical landscape.

Remembering Paulo S. Bretones: A passionate Astronomy Educator and Researcher

Professor, Dr Urban Eriksson

Division of Physics Education Research, Dept. of Physics and Astronomy, Uppsala University, Uppsala, Sweden

Abstract

I met Paulo S. Bretones for the first time in Vienna 2018 at the International Astronomical Union (IAU) General Assembly. This was the beginning of a very fruitful collaboration that led to us organizing two international AstroEdu conferences, and start the international Astronomy Education Journal. The conferences have been very successful in bringing together astronomy educators and astronomy education researcher where we have a forum to discuss with our peers and colleagues on interesting and intricate matters concerning astronomy education and research. Paulo was a driving force to make these conferences happened. The situation was similar with the AEJ, launched at the AstroEdu conference in 2019, where Paulo and I saw a great need for astronomy educators and researchers to publish their work. At the time, and now, there is no other journal that meets these needs. Paulo was pushing me forwards as new editor together with him, and I learned so, so, much from him. He was also involved in the initiative Astronomy Days in Schools.

It was with great sadness that I, during the end of 2022 understood that Paulo was unwell and by the beginning of 2023 our otherwise weekly meetings ceased; Paulo could not continue the fantastic work he had done.

We have all lost a very good and appreciated colleague. Paulo, we miss you deeply and will always remember you. Thank you for all we have learned from you and all the laughter over the years.

May you rest in peace among the stars.

DIDACTICS OF TEACHING ASTRONOMY AND ASTROPHYSICS

Dr Afrodita Liliana Boldea

National Institute for R&D in Physics and Nuclear Engineering, Bucharest, Romania. University of Craiova, Romania

Abstract

Education has a purpose that by the terms in which it is formulated has the purpose of forming the profile of the human personality.

In education it is operated with purposes that are related to the dimensions of education, of each level of schooling, the curricular cycles. In the didactic activity, in order to carry out the teaching-learning process the teacher uses different methods, depending on the specific and framework of the topics. The introduction in the educational environment, in Astronomy and Astrophysics discipline, of the information technologies of online communication, of type e-learning, along with the traditional teaching methods according to the principles of didactics, had a major impact on the didactic strategies and the forms of organization of training in the education process.

This work aims to present a didactic project for teaching a lesson in Astronomy and Astrophysics discipline and the implementation of a modern teaching method, as efficient, through the e-Learning Moodle platform, to teach an Astronomy and Astrophysics course, for students. The composition of the didactic project regarding the process of teaching-learning-evaluation to Astronomy and Astrophysics was carried out together with the students from University of Craiova, Faculty of Sciences, during the participation at the course of Didactics of the domain and development in specialization didactics, Master, I year . The experimental part of the lesson taught is represented by the processing with the Astrometrica software, a image package of asteroids, taken with the INT telescope, Isaac Newton Telescope, from La Palma, Spain.

What Does Moroccan Astronomy Owe to the Oukaimeden Observatory and What Are the Future Perspectives?

Zouhair Benkhaldoun

Oukaimeden Observatory, Cadi Ayyad University, Morocco

Abstract

Morocco's journey in advancing astronomy commenced in the late 1980s with the formation of a group of astrophysicists within the National Center for Scientific and Technical Research (CNRST) in Rabat. These researchers, educated abroad, established the Laboratory of Astronomy and Geophysics (LAG), marking Morocco's trajectory towards a comprehensive research center. Despite initial hurdles, the Laboratory of High Energy Physics and Astrophysics (LPHEA) emerged in 1999, attaining the status of the leading research center at Cadi Ayyad University by 2009. Their dedication led to the formal recognition of the Oukaimeden Astronomical Observatory as a research center in 2009. Subsequently, the Oukaimeden Observatory ascended as one of Africa's premier astrophysical research infrastructures, with international collaborations augmenting research endeavors.

In this contribution, I will present advancements achieved by our team in diverse areas of astrophysics. These include site qualification, exoplanet observation, high-resolution interferometry, solar physics, planetary sciences, and small solar system bodies research, wherein our team excelled.

Looking ahead, Moroccan astronomers aim to expand into space sciences, particularly in Space Situational Awareness (SSA) and Space Weather. These themes promise advancements in understanding celestial phenomena and their impacts on Earth. With ongoing international collaborations and a focus on research and innovation, Morocco's astronomical pursuits are poised to continue flourishing globally.

Research on access, use and effective exploration of astronomical data from sonification

Johanna Casado

Instituto de Bioingeniería, Facultad de Ingeniería, Universidad de Mendoza

Abstract

Data analysis in space sciences has been performed exclusively visually for years, despite the fact that the largest amount of data belongs to non-visible portions of the electromagnetic spectrum. This, on the one hand, limits the study of the unknown to the current resolution possibilities of the screens, and on the other hand, it excludes a group of people who present some type of visual disability. Taking into account the aforementioned, and the barriers that people with disability face to achieve academic studies and stable jobs, the present investigation focuses on new modalities of access to the data, but taking into account the accessibility and inclusion from the beginning. It has been shown that multimodal perception (use of more than one sense) can be a good complement to visual exploration and understanding of complex scientific data. This is especially true for astrophysical data, composed of a sum of different oscillatory modes resulting in the final complex data array. This proposal focuses on the human ability to adapt to data and interaction with sound, in order to analyze data sets and produce an application aimed at leveling the possibilities of access to information in the field of physics and astronomy for people with disabilities. In addition, it proposes the study of scientific and technological capacities for the generation of tools with a novel approach, focused on the user and oriented to: a specific social problem, the use of free programming languages and the design of infrastructure to improve inclusion.

SciAccess: Best Practices for Accessibility in Astronomy Education and Outreach

Anna Voelker[1], Caitlin O'Brien[2]

[1]SciAccess, Inc. [2]SciAccess, Inc. | The Ohio State University

Abstract

SciAccess is an award-winning nonprofit dedicated to advancing disability inclusion and equity in STEM education, research, and outreach. This poster will showcase accessible astronomy best practices that have been discovered through the following:

(1) The SciAccess Conference, an annual international conference bringing together STEM educators, astronomers, disability advocates, and students to design and disseminate best practices in STEM accessibility.

(2) The Zenith Mentorship program, which provides blind high schoolers with astronomy mentorship and the opportunity to engage in experiential learning through tactile 3D models, sensory astronomical graphs, and data sonification.

(3) AstroAccess, which works with disabled individuals to research universal design in space architecture, making concrete advancements in access to space exploration.

(4) Solstice, which uses a state-of-the-art portable planetarium system to bring immersive, engaging astronomy outreach in the form of planetarium shows to underserved communities.

This poster will highlight key takeaways from the above programs, offering concrete guidance on accessible astronomy best practices and outreach strategies. This will include an overview of accessible astronomy resources, where attendees will be invited to interact with 3D printed models of astronomical bodies to demonstrate that tactile resources designed for blind users can improve comprehension for all people. Participants will leave with a new understanding of astronomy accessibility and the resources and connections they need to play a part in engaging the next generation of diverse scientists and researchers.

The Africa Radio Astronomy Programme

Mrs Carla Mitchell

South African Radio Astronomy Observatory

Abstract

The new Africa Radio Astronomy Programme (ARAP) is broader than the original African VLBI Nework (AVN) and, although it still incorporates VLBI implementation activities, it also aims to capitalise on the achievements to date while reflecting on the challenges encountered in order to design a coherent programme that will accelerate the SKA Africa partnership objectives. The new Africa Radio Astronomy Programme strategy was approved in June 2023. Implementation will be customised to the basic needs and agendas of each Africa Partner Country (APC) towards technology, industry and academic advancement. The vision of the programme is for the sustainable establishment of African science and technology networks and skills, and growth of science and technology capacity in the SKA APCs. Next steps include the roll out of the TART training instruments, to be distributed to each APC during 2024, high performance computing and data intensive analytics implementations and training, and the 3-metre interferometer dishes will be designed, manufactured and installed in each country through the period from 2024 to 2026. These instruments will be used for interferometry and single-dish science and a 5 stage training programme will be implemented in partnership with DARA. These and other activities and partnerships are based on three main pillars: Human Capital Development, Research and Technology Infrastructure; and Funding, Governance and Partnerships. Each pillar is centred around specific and intentional activities, that are aimed at solidifying the impact of the strategy on the development of astronomy and its resultant socio-economic impacts in the partner countries.

Unlocking the African Sky: Strategies for maximizing the socio-economic development

Mr Takalani Nemaungani

Department of Science & Innovation

Abstract

Africa boasts a rich astronomical heritage and some of the darkest skies on Earth, offering unparalleled potential for astronomy education, outreach, and economic development. This presentation explores a multifaceted approach to unlocking Africa's astronomical potential, highlighting the vital work of organisations like SAAO, SARAO, and the Astro-Tourism Strategy by the Department of Science and Innovation and Department of Tourism.

Astronomy is contributing to skills development, technological development through local innovations, job creation, improvement of educational outcomes and outreach. Online resources and digital learning platforms further democratize access to astronomy education, and initiatives like SARAO's robotics program and school bursaries provide crucial support to the next generation of scientists and astronomers.

Public engagement is fostered through a variety of initiatives. SAAO's Open Nights allow citizens to directly experience the cosmos. Further bridging the gap, SARAO's "Mission MeerKAT" cartoon series makes radio astronomy accessible and engaging through a fun and informative format. Initiatives like the SALT Collateral Benefits Programme leverage SAAO's resources to develop educational materials and support local communities, fostering a deeper public engagement with astronomy.

Astro-tourism aims to go beyond simply viewing the night sky by integrating traditional African starlore and cultural knowledge into astro-tourism experiences creating a unique and meaningful connection for visitors. The Astro-Tourism Strategy provides a framework for developing sustainable astro-tourism projects that benefit local economies while preserving Africa's unique astronomical heritage.

The success of these initiatives hinges on collaboration between government departments, research institutions, and local communities.

Astro-Reach in Kenyan Schools

Mr Kenneth Monjero

Fun and Education Global Network

Abstract

Astro-Reach is an astronomy outreach program tailored for primary schools in Kenya, aiming to stimulate curiosity and empower learners through practical engagement with celestial phenomena. By employing interactive exhibits, hands-on activities, and captivating demonstrations, Astro-Reach provides students with immersive experiences that demystify the cosmos and inspire a passion for space exploration. Central to its approach are locally designed space suits, representing cultural diversity and inclusivity in STEM fields. Through Astro-Reach, students not only gain knowledge of astronomy but also develop a deeper appreciation for scientific inquiry and the wonders of the universe, fostering a new generation of curious and empowered learners.

11 CAP Conferences strong – C2 updates from the largest international conference forastronomy communication

Marieke Baan[1], Oana Sandu Barbulete[2], Sylvie Vauclair[3]

[1]NOVA, University of Amsterdam. [2]President Commission C2. [3]Vice-president Commission C2

Abstract

The Communicating Astronomy with the Public (CAP) Conference is the only large-scale, international conference for astronomy communication. The conference is targeted towards professionals from science communication, informal education, planetaria and science centres, as well as professional and amateur astronomers, journalists and creative personalities. This year's CAP2024 in Toulouse, France, was the 11th in the series of conferences organised by the International Astronomical Union (IAU), through Commission C2 Communicating Astronomy with the Public, and the IAU Office for Astronomy Outreach (OAO). Since 2003, CAP conferences have facilitated the exchange of ideas and best practices. The conference helps strengthen the local community of professionals by connecting them to the global network. In this talk, we will present an overview of the conference and how it has evolved over the years.

The present state of Higher Education in the Gaza strip and the West Bank with a focus on astronomy

Jamal Mimouni

Department of Physics, University of Constantine1, Algeria

Abstract

This presentation will highlight the severe challenges faced by the academic community in conflict zones, with a specific focus on the Palestinian occupied territories. The ongoing conflict in the Gaza Strip and the West Bank has had profound implications on various aspects of life, including higher education. In the Gaza Strip, most of the educational infrastructure has been devastated, and universities and institutions of higher learning have been systematically destroyed. A stark example of this devastation is the fate of the "UNESCO Palestine Chair in Astronomy, Astrophysics & Space Sciences," which we personally inaugurated in 2012 in Gaza alongside UNESCO chair holder Prof. Suleiman Baraka. The center was obliterated in the recent events, along with Gaza Islamic University, where it was located, and Al-Aqsa University, where the classes were held. All the students working at the center had their academic lives disrupted as they became refugees, and many were tragically killed. This presentation underscores the necessity of sanctuarizing academic institutions, much like hospitals and other vital facilities, to protect them from the ravages of conflict. The dire situation faced by the inhabitants of the Gaza Strip and the West Bank. It also highlights the urgent need for international support and solidarity to rebuild educational infrastructure in these regions.

Government and science engagement sector contribution in astronomy

Shadrack Mkansi

NRF-SAASTA. ASSA Jhb Central. Beijing Global Network of Science Festivals (BGNSF). ICORSA. SAASTEC Ex-Officio

Abstract

Astronomy is an easily accessible scientific area with a naturally accessible resource. The science engagement sector, majority of whom are science centres, are one of the great contributors to the communication of astronomy in the country. Science centres are found in all nine (9) provinces of the country. They are easily accessible to most community members because they are found within various economic levels of communities. Through science centres and other science engagement community astronomy has been communicated widely in most communities in all 52 municipalities in the country. This paper will show the landscape of the science engagement sector in the country and then give a special focus on the distribution of science centres. We will look at the impact this has in the astronomy subject area. There are resourcing challenges but this paper will show how the government resources were able to provide capacity for science engagement community to communicate astronomy. The impact of the types of resources provided by government and other sectors in astronomy awareness will be covered. Lastly we will look at how resources can be maximised to ensure that we have a continuous astronomy engagement throughout the country in all municipalities and all communities. The paper will show how government support changed the level of astronomy awareness to be where it is today.

Acceleration of Ultra-high-energy Cosmic Rays in Relativistic Jets of Giant Radio Galaxies

Prof Hyesung Kang[1], Prof Dongsu Ryu[2], Dr. Jeongbhin Seo[3]

[1]Pusan National University. [2]Ulsan National Institute of Science and Technology. [3]Los Alamos National Laboratory

Abstract

In this study, we investigate cosmic ray (CR) acceleration processes within FR-I and FR-II radio galaxies through a series of relativistic hydrodynamic simulations, encompassing relativistic jets characterized by varying powers and bulk Lorentz factors. Monte Carlo simulations are subsequently employed to model the transport, scattering, and energy changes of CR particles, facilitating the calculation of particle acceleration within the simulated jet-induced flows. Our results indicate that diffusive shock acceleration in the jet-spine and backflow energizes CRs up to approximately 1 EeV. At higher energies, however, relativistic shear acceleration across the jet-backflow interface becomes more significant. The time-asymptotic energy spectrum of CR particles escaping from the jet system can be represented by a double power law with an extended exponential cutoff. We demonstrate that the charge-dependent break energy is primarily governed by the jet power, but with weak dependencies on the jet size and background density. Notably, the conventional exponential cutoff is extended through the energy boost achieved via non-gradual shear acceleration, proportional to the square of the mean Lorentz factor of the jet. Our analysis demonstrates that more relativistic jets with higher bulk Lorentz factors can generate energy spectra extending to higher energies, resulting in elevated particle flux and a lighter mass composition at the high-energy tail. These findings provide valuable insights into the acceleration of ultra-high-energy cosmic rays within giant radio galaxies.

X-Ray Polarization Variability of High Spectral Peak BL Lacertaes: Cases of 1ES 1959+650 and PKS 2155--304

Dr. Jin Zhang

Beijing Institute of Technology

Abstract

The high-energy-peaked BL Lacertae objects (HBLs) are the main targets of the Imaging X-ray Polarimetry Explorer (IXPE) for investigating the mechanisms of radiation and particle acceleration in jets. In this paper, we report the first IXPE observations of two HBLs, 1ES 1959+650 and PKS 2155--304. Both sources exhibit X-ray polarization with a confidence level exceeding 99%, as well as significant variability in polarization across different time intervals and energy ranges. Notably, PKS 2155--304 demonstrates the highest X-ray polarization among all blazars detected by IXPE within its entire energy band (2--8 keV), with a polarization degree of Π_X=21.9%±1.9% (MDP_{99}=6.0%). An even higher polarization is observed in the 3--4 keV band, reaching Π_X=28.6%±2.7 (MDP_{99}=8.1%) with a confidence level of 10.8σ. Furthermore, no polarization is detected above 5 keV energy band. For 1ES 1959+650, the highest detected polarization degree in the 2--8 keV band is Π_X=12.4%±0.7% (MDP_{99}=2.2%), with an electric vector position angle (EVPA) of Ψ_X=19.7°±1.6°. The X-ray polarization of 1ES 1959+650 exhibits evident variability, accompanied by the variations of Ψ_X, flux, spectrum, and energy bin. We discuss possible implications of these observational findings, including the variability in polarization, rotation of EVPA, and transition between synchrotron and synchrotron-self-Compton. We speculate that the X-rays observed during different IXPE observations originate from distinct regions in the jet and may involve diverse mechanisms for particle acceleration.

A Comprehensive Multi-Frequency Analysis of the Radio Phoenix in the Abell 85 Cluster

Ramij Raja[1], Majidul Rahaman[2], Prof. Abhirup Datta[3], Prof. Oleg Smirnov[1,4]

[1]Rhodes University. [2]National Tsing Hua University. [3]Indian Institute of Technology Indore. [4]South African Radio Astronomy Observatory

Abstract

Radio phoenixes are intricate and filamentary diffuse radio sources discovered in both merging and relaxed clusters. It has been suggested that these sources form due to the adiabatic compression of aged Active Galactic Nucleus (AGN) plasma within shock waves. Previous studies on these sources primarily focused on integrated spectral indices, which were found to be steep and exhibited a curved spectrum. In this study, we conducted a multi-frequency investigation of the radio phoenix in the Abell 85 cluster. Utilizing sensitive high-resolution observations, we identified finer filamentary structures that had previously gone unnoticed. Resolved spectral index maps of the radio phoenix were generated across frequencies ranging from 148 to 1280 MHz. Analysis of filament orientation and spectral index gradient suggests a potential direction of shock motion from northeast to southwest. The integrated spectral index of the radio phoenix was notably steep, with a break observed around 700 MHz, indicating recent re-energization of fossil electrons. Furthermore, filament spectral indices were found to be less steep compared to non-filamentary regions, suggesting higher energy injection in the filaments. These findings support the adiabatic shock compression mechanism as the likely explanation for the observed features in the radio phoenix in the Abell 85 cluster.

White dwarfs in Gaia survey to constrain the fine-structure constant

Dr. Surajit Kalita[1], Mr. Akhil Uniyal[2], Prof. Sayan Chakrabarti[3]

[1]University of Cape Town, South Africa. [2]Tsung-Dao Lee Institute, Shanghai Jiao Tong University, China. [3]Indian Institute of Technology, Guwahati, India

Abstract

This abstract is primarily based on MNRAS 527 (2024) 232 and ApJ 949 (2023) 62. Understanding various physical mechanisms requires an understanding of fundamental constants, however, measurements of these constants are subject to error due to experimental constraints. Researchers have proposed several bounds on fundamental constants based on a variety of experiments and observations. These constraints are different primarily because of the energy scale of the systems used in the studies. We investigate the impact of system temperature and the effect of the underlying theory of gravity on these uncertainties using white dwarfs observed in the Gaia data survey. In my talk, using the structures of these white dwarfs, I will show that variations in temperature as well as the underlying theory of gravity can affect the accuracy of measurements for fundamental constants such as the fine-structure constant and the proton-to-electron mass ratio. This exploration emphasizes the importance of considering the energy of a system when putting bounds on fundamental parameters.

Energy-dependent polarization of Gamma-Ray Bursts' prompt emission with the POLAR and POLAR-2 instruments

Nicolas De Angelis

INAF-IAPS Roma, via del Fosso del Cavaliere 100, I-00133 Roma, Italy

Abstract

Gamma-ray bursts (GRBs) are among the most powerful and violent events in the Universe. Despite half a century of observations of these transient sources, many open questions remain about their nature and the physical emission mechanisms at play. Polarization measurements of the GRB prompt emission have long been theorized to be able to answer most of these questions.

To characterize the polarization of these prompt emissions, a compact Compton polarimeter, called POLAR, has been operated for 6 months on the Tiangong-2 space lab starting September 2016. The instrument detected 55 GRBs as well as several pulsars. Time-integrated polarization analysis of the POLAR GRB catalog has shown that the prompt emission is lowly polarized or fully unpolarized. However, time-resolved analysis depicted strong hints of an evolving polarization angle within single pulses, washing out the polarization degree in time-integrated analyses.

Here we will present the first energy-resolved polarization measurements of GRB prompt emission. The novel analysis, performed on several GRBs using the POLAR data, will provide new insights and alter our understanding of GRB polarization. The analysis was performed using the 3ML framework to fit the polarization parameters as a function of the energy in parallel to the spectral parameters. Although limited by statistics, the results could provide a very relevant input to disentangle between existing theoretical models. The presentation will conclude with prospects for energy-resolved polarization measurements using the upcoming POLAR-2 mission.

A polarized view of the pulsar wind nebulae with IXPE

Dr. Fei Xie

Guangxi University, China

Abstract

Pulsar wind nebulae (PWNe) are powerful sources of non-thermal X-ray radiation, which is intrinsically polarized due to synchrotron emission. The magnetic field strength and structure in these sources play a crucial role in shaping their dynamics, energetics and evolution, as well as in accelerating particles to very high energies. X-ray polarimetry can provide unique insights into understanding the local orientation and degree of order of the magnetic field, as well as the distribution and spectrum of the emitting particles. In this talk, I will review the current status and future prospects of X-ray polarimetry applied to extended source PWN, with a focus on the Imaging X-ray Polarimetry Explorer (IXPE) mission, which is a NASA/ASI explorer launched in December 2021.

A study of the polarization and RM of pulsars in globular clusters with MeerKAT and FAST

Dr Lei Zhang

National Astronomical Observatories, Chinese Academy of Sciences

Abstract

Magnetic fields are found in astronomical objects of all scales. One class of objects where magnetic fields have been very hard to observe and study is globular cluster (GC). There is very limited evidence of intracluster medium within GCs. For this reason traditional techniques to detect magnetic fields like synchrotron emission or rotation measure (RM) from the gas are not effective. The limited number of studies that have focused on the magnetic fields towards GCs used information derived from pulsars. In the last few years, the total known population of GC pulsars has increased dramatically, jumping from about 150 objects known in 2018, to more than 300 known today. Such a surge in new discoveries and the consequent "renaissance" of the field has been possible mainly thanks to two major radio facilities that have recently been built: the FAST radio telescope in the northern hemisphere and the MeerKAT radio telescope in the southern hemisphere. In the talk, I will present a study of the polarization and RM of pulsars in globular clusters with MeerKAT and FAST. The goal, among others, is to study the magnetic field in the clusters and small scale magnetic field in the Galactic disk and halo.

An Evolutionary Picture of Fast Radio Bursts

Dr. Di Li

NAOC

Abstract

The Five-hundred-meter Aperture Spherical radio Telescope (FAST) has been in operation for four years. Based on a novel high-cadence CAL injection technique, we have designed the Commensal Radio Astronomy FAST Survey (CRAFTS), which realizes, for the first time at any major facility, simultaneous data recording of pulsar search, HI imaging, HI galaxies, and transients (FRB and SETI). CRAFTS has discovered ~200 pulsars, ~10 FRBs including the only persistently active repeater FRB 20190520B, and ~5000 d^2 HI images with 1% calibration consistency, 5-10 times better than what is available from Arecibo. I will discuss FAST's science highlights regarding FRBs, particularly a new evolutionary picture. Critical pieces of evidence include a 10% drop of FRB 121102's DM on a decade time scale, the frequency evolution of active repeaters well described by a single physical parameter sigma_RM, the B field reversal around 190520B, and the intriguing correlation of sigma_RM with PRS. We are starting to reveal a likely explosive event associated with FRBs' origin and their changing complex plasma environments.

A spectral and timing study of MAXI J1820+070 during itsoutburst

Mr. Kyle Solomons[1,2], Dr. Sunil Chandra[2,3]

[1]University of Cape Town. [2]South African Astronomical observatory. [3]North-West University

Abstract

This study investigates the spectral and timing characteristics of MAXI J1820+070, a Black Hole X-ray binary, during its 2018 outburst utilizing data from NuSTAR, NICER, and Swift-XRT. Our findings reveal valuable insights into spectral properties, including a power-law index of ~1.6 and an inner disk temperature peaking at 0.8 keV. Furthermore, we identify quasi-periodic oscillations (QPOs) and provide evidence supporting their origin in the corona. Additionally, dynamic hard and soft time lags are observed, indicating a vertically expanding and contracting corona at different stages of the outburst. Notably, we detect potential absorption features between 6.9-7.3 keV, suggesting the presence of outflows. Our comprehensive analysis tracks the evolution of temporal and spectral parameters throughout the outburst, contributing to a deeper understanding of the system's behaviour."

Polarized X-ray Signals from Neutron Star Surfaces

Dr. Matthew Baring[1], Dr. Hoa Dinh[1], Dr. George Younes[2], Dr. Kun Hu[3]

[1]Rice University, Department of Physics and Astronomy, Houston, TX 77005, USA. [2]NASA's Goddard Space Flight Center and University of Maryland, Baltimore County, USA. [3]Physics Department, Washington University, St. Louis, MO 63130, USA

Abstract

The intense magnetic fields of neutron stars generate strong anisotropy and polarization of radiation emanating from their surfaces. These emission properties are sensitive to the magnetic field orientation relative to the local zenith, and thus on the hot spot position on the surface. Therefore, phase-resolved intensities and polarizations depend on the angle between the magnetic and spin axes of a star, and an observer's viewing direction. In this talk, we present results from a Monte Carlo simulation of neutron star atmospheres that uses a complex electric field vector formalism to treat polarized radiative transfer due to magnetic Thomson scattering. The atmospheres possess temperature gradients via their hydrostatic equilibrium. General relativistic and QED vacuum birefringence influences on the propagation of light from the stellar surface to a distant observer are taken into account. We outline a range of theoretical predictions for pulse profiles at different X-ray energies, focusing on magnetars and also neutron stars of lower magnetization. A general anti-correlation between intensity and polarization degree is observed, which is naturally connected to the scattering cross section physics. By comparing these models with observed intensity and IXPE polarization pulse profiles for select magnetars, and light curves for other isolated neutron stars, we obtain constraints on the stellar geometry angles and the size and location of the hot spots. For magnetars, we outline how polarization measures might inform us about the level of toroidal twist in the magnetospheric field.

Revealing Blazar Jets: A Review of High-Energy Polarimetry of Jets

Ms Lenté Dreyer, Prof. Markus Böttcher

North-West University

Abstract

This presentation will explore the critical role of high-energy polarimetry in our current understanding of blazar jets. The Imaging X-ray Polarimetry Explorer (IXPE), launched in 2021, elucidated high-energy polarimetry. The detection of high degrees of polarization in X-rays suggests ordered magnetic fields and indicates that particle acceleration in blazar jets may proceed through coherent processes like shocks rather than diffusively. IXPE's capability, combined with simultaneous multiwavelength polarization measurements, provides insights into the magnetic topology and the physical processes driving jet dynamics. For instance, the orphan optical polarization swing seen in PG 1553+113 and its different polarization degrees in the X-ray, radio, and optical bands point to emission regions that are either entirely separate or only partially overlapping. A rotation of the polarization angle in the X-rays seen in Markarian 421 supports the idea that helical magnetic fields exist in blazar jets. The presentation will conclude by examining the prospective advancements in jet polarimetry, considering the contributions expected from IXPE, forthcoming instruments, and the ongoing application of Monte Carlo methods to investigate high-energy polarization due to anisotropic Compton scattering, thereby offering pivotal insights into the complex mechanisms operating within blazar jets.

Turbulence induced fast magnetic reconnection: high resolution 3D MHD simulations of self-sustained turbulent current sheets

Giovani Heinzen Vicentin[1,2], Dr. Grzegorz Kowal[1], Dr. Elisabete de Gouveia Dal Pino[1], Dr. Alex Lazarian[3]

[1]Universidade de São Paulo. [2]Princeton University. [3]University of Wisconsin–Madison

Abstract

Magnetic reconnection plays a crucial role in converting magnetic energy into kinetic and thermal energy in the plasma, being a powerful mechanism to explain solar, pulsar nebulae and AGN flares, heating and particle acceleration. In this work (Vicentin et al. 2024), we study the properties of turbulence induced reconnection using very-high-resolution 3D MHD simulations for a vast parametric space, reaching Lundquist numbers of 10^6. We demonstrate that an initial perturbation in the current sheet drives self-sustained turbulence in the domain of our simulations, providing fast reconnection rates of V_{rec} ~ 0.03-0.08 V_A, where V_A is the Alfvén velocity. These reconnection rates are larger and grow faster than the ones generated solely by resistive tearing mode (plasmoid) instability measured from 2D and 3D PIC/MHD simulations (Huang and Bhattacharjee, 2010, 2016). Notably, the reconnection rates obtained in this work are compatible to the ones obtained in local classical 3D MHD simulations of current sheets (Kowal et al. 2009, 2017, for lower Lundquist numbers) and in 3D (GR)MHD simulations of turbulent accretion flows and relativistic jets (Kadowaki et al. 2018, 2021; Medina-Torrejon et al. 2021, 2023), where no evidence of plasmoid formation was found. In our simulations the reconnection rate reaches a steady state at the same time that turbulence is fully developed. They evidence the independence of the reconnection rate on the Lundquist number, as first proposed by Lazarian and Vishniac (1999), and a weak dependence of V_{rec} on the plasma-beta (the ratio between thermal and magnetic pressure in the plasma).

Machine-Learning Enhanced Photometric Analysis of the Extremely Bright GRB 210822A

Ms. Camila Angulo-Valdez[1], Dr. Rosa Becerra[2], Dr. Margarita Pereyra[3]

[1]Instituto de Astronomía, Universidad Nacional Autónoma de México, Ciudad de México, México. [2]Dipartimento di Fisica, Universita degli Studi di Roma Tor Vergata, Roma, Italia. [3]Instituto de Astronomía, Universidad Nacional Autónoma de México, Ensenada, Baja California, México

Abstract

In this talk, I will present analytical and numerical models of the bright long GRB 210822A at z=1.736. The intrinsic extreme brightness exhibited in the optical, which is very similar to other bright GRBs (e.g., GRBs 080319B, 130427A, 160625A 190114C, and 221009A), makes GRB 210822A an ideal case for studying the evolution of this particular kind of GRB.

We use optical data from the RATIR instrument, as well as Swift/UVOT, and X-ray data from the Swift/XRT instrument. The temporal profiles and spectral properties during the late stages align consistently with the conventional forward shock model, complemented by a reverse shock element that dominates optical emissions during the initial phases (T<300 s). We observe a break in the light curve at T=80000 s that we interpreted as evidence of a jet break, which constrains the opening angle to be about θ_j = (3-5) degrees.

Finally, we apply a machine-learning technique to model the multi-wavelength light curve of GRB 210822A using the AFTERGLOWPy library. We estimate the angle of sight θobs=(6.4 ± 0.1) × 10-1 degrees, the energy E_o= (7.9 ± 1.6)× 10^{53} ergs, the electron index p=2.54 ± 0.10, the thermal energy fraction in electrons ε_e = (4.63 ±0.91) × 10^{-5} and in the magnetic field ε_B= (8.66 ± 1.01) × 10^{-6}, the efficiency χ = 0.89 ± 0.01, and the density of the surrounding medium n_o = 0.85 ± 0.01 cm^{-3}.

Abstract

Blazars emit strongly polarised (nonthermal) synchrotron emission detected in the radio through optical-UV/X-ray observations. The dusty torus, broad line region, accretion disk and host galaxy radiate unpolarised thermal emission. Their presence is usually visible in the total polarisation degree observed, because they dilute the synchrotron polarisation. However, in some observations a polarisation decrease is also discernible towards longer wavelengths. This can be described by partially ordered magnetic fields downstream from a shock in the jet. We present co-ordinated observations from the SALT, H.E.S.S., *Fermi* -LAT, *Swift*-XRT, ATOM and LCO. From this, we deduce the presence of different emission zones (one, two and multiple domains) required to simultaneously model the polarisation degree and multi-wavelength spectral energy distributions.

Abstract

Gamma-ray Bursts (GRBs) are produced by highly relativistic beamed jets powered by a compact central engine. The nature of the central engine and the role of magnetic fields are still open questions to be addressed by high energy polarimetry of the prompt emission, which is widely believed to be the key to disentangling jet outflow composition, emission mechanisms, and energy dissipation. Each physical process gives different degrees of polarized light - low in thermal radiation, and high in synchrotron radiation with a structured magnetic field in the jet. In the past few years, high-energy X-ray polarimeters, AstroSat CZTI (100-600 keV), and POLAR (50-500 keV) have measured the polarization of more than 32 GRBs. Two bursts - namely GRB 170202B and GRB 161218B - were detected by both CZTI and POLAR. We undertake joint analysis of these two GRBs with PolPy, a universal tool developed on the 3ML framework. We forward-fold the model using Bayesian time-integrated analysis, and perform joint spectral fit from various missions, cross-calibrating the polarization using CZTI and POLAR. In this talk, I will showcase the results of our joint spectro-polarimetric fit, and discuss implications for emission models of GRBs.

Exploring AGN coronae through X-ray polarimetry: insights from IXPE observations

Mr. Daniele Tagliacozzo

Università degli Studi Roma Tre

Abstract

The Imaging X-ray Polarimetry Explorer (IXPE) observed three unobscured radio-quiet AGN during its initial two years of operation (NGC4151, IC 4329A and MCG-05-23-16), retrieving two detections and one tight upper limit. Here we present the results of the X-ray polarimetric analyses of these sources, together with simultaneous XMM-Newton and NuSTAR data. The synergy between these instruments has been fundamental to constrain the physical properties of the hot corona and to assess its geometry, which may hold clues to its physical origin. The outcomes of extensive Monte Carlo simulations will also be presented, exploring insights gained through comparison with real data. Present and future polarimetric observations remain pivotal for understanding the nature of AGN coronae.

Early Evolution of Long Gamma-Ray Burst Jets: Ultra-Relativistic Hydrodynamic Simulations

Professor Dongsu Ryu, Mr. Seonho Kim, Professor Kyujin Kwak

UNIST (Ulsan National Institute of Science and Technology), South Korea

Abstract

Gamma-ray bursts (GRBs), one of the most energetic phenomena in the universe, involve ultra-relativistic jets with Lorentz factors reaching several hundred. With such large Lorentz factors, simulation studies of these jets require robust codes that can properly handle ultra-relativistic flows. Using a newly developed relativistic hydrodynamic code of high accuracy, we perform three-dimensional simulations of ultra-relativistic jets with Lorentz factors up to ~ 100, to explore the early evolution and structure of long GRB (LGRB). Our simulations incorporate realistic LGRB environments and investigate models with varying jet Lorentz factor, opening angle, density, and pressure, as well as varying ambient medium properties. In the simulations, we identify four distinct regions: the spine, the shocked spine, the shocked ambient medium, and the ambient medium from the interior of the jet outwards. We find that the structure of GRB jets differs from that of the relativistic jets in radio galaxies. Notably, the larger Lorentz factors and non-zero opening angles of GRB jets lead to wider spines. Additionally, instead of the back-flow cocoon, the shocked spine with forward moving flow develops. We analyze shocks, shear, and vorticity in the simulations, quantifying physical properties such as the probability distribution functions of shocks and relativistic shear and the energy dissipation due to shocks and turbulence. Our analysis indicates that shocks and shear predominantly develop within the shocked spine, suggesting that particle acceleration within LGRBs would occur primarily in this region.

Abstract

The recent confirmation of black hole births in GRB 130427A and GRB 190114C, coupled with parallels drawn from GRB 180720B, provides a robust foundation for studying the properties of the black hole in GRB 220101A. In our approach we consider the "inner engine" as a rotating Kerr BH of mass M and dimensionless spin parameter α, a magnetic field of strength B0 aligned and parallel to the rotation axis, and a very low-density ionized plasma. We show that in GRB 220101A the BH mass M = 6.15M⊙, α = 0.95, Mirr = 4.98M⊙ and B0 ≈ 109G can lead to a high-energy (≥ GeV) luminosity of 10^51ergs−1 .

Understanding the nature of the Partially screened Gap in Pulsars from radio observations.

Dr. Rahul Basu[1], Prof. Giorgi Melikidze[1,2], Dr. Dipanjan Mitra[3,1], Dr. Jaroslaw Kijak[1]

[1]Janusz Gil Insitute of Astronomy, University of Zielona Gora, Poland. [2]Evgeni Kharadze Georgian National Astrophysical Observatory, 0301 Abastumani, Georgia. [3]National Centre for Radio Astrophysics - Tata Institute of Fundamental Research, India

Abstract

The single pulse sequence from pulsars is dynamic in nature and shows a number of interesting phenomena like subpulse drifting, mode changing, nulling, periodic intensity modulation, periodic nulling, etc. A non-stationary outflow of plasma is setup along the open magnetic field line region of pulsars due to sparking discharges above the polar cap. The sparking process is thermally regulated due to discharge of ions from the heated polar cap surface forming a partially screened gap (PSG). The magnetic field near the pulsar surface are highly non-dipolar in nature. The sparks undergo variable **E✕B** drift in the PSG that gives rise to subpulse drifting.

In this talk we present the results of our observations, primarily using the GMRT, of the single pulse behaviour from more than 200 pulsars. We have characterised the nature of subpulse drifting, nulling and emission mode changing seen in a large fraction of these sources. We have also demonstrated that periodic intensity modulations and periodic nulling are a new class of emission feature in pulsars with a distinct physical origin than subpulse drifting. The measurements of subpulse drifting features can be be used to constrain the sparking process in PSG. Nulling, mode changing and periodic modulations require rapid transitions between different emission states. Hall and thermoelectric oscillations can perturb the heated polar cap magnetic field to alter the sparking process in the PSG, resulting in the observed transitions of the radio emission states.

Abstract

X-ray binaries are key sources for understanding the accretion and ejection processes around compact objects. Multiwavelength monitoring of these sources showed that the X-ray emission comes from the inner regions of the accretion disk. Parallely, optical spectroscopy gives valuable information about the companion star parameters. Resolving the intricate geometry of X-ray binaries requires precise measurements of the polarimetric properties of the source. Since the launch of the Imaging X-ray Polarimetry Explorer (IXPE) in 2021, constraining the shape of the corona around stellar-mass black holes is now possible. We present the first X-ray polarimetric observation of the low-mass X-ray binary 4U 1957+115 in its persistent high/soft spectral state, performed with IXPE in May 2023. These unique measurements enabled estimates of the BH spin and the inclination of the system.

X-ray polarization properties across black-hole accretion states

Jiří Svoboda

Astronomical Institute of the Czech Academy of Sciences, Prague, Czech Republic

Abstract

Accreting black holes represent unique laboratories to study physics under extreme gravity. The X-ray polarization measurements put constraints on the geometry of accretion flow and may also provide independent estimates of the black hole spin when the matter accretes in the form of a thin accretion disk. A recently launched Imaging X-ray Polarimetry Explorer has observed about a dozen accreting stellar-mass black holes in various accretion states. In my talk, I will discuss how the X-ray polarization properties depend on the accretion state and which observational constraints we got from the observations.

The culprit for the termination of Mars'magnetic field: Dark Matter

Ms Javeria Makda, Dr Geoff Beck

University of the Witwatersrand

Abstract

In this work we derive limits on the WIMP-nucleon scattering cross-section by comparing the potential heat flow within the Earth from Dark Matter capture and subsequent annihilation to the observational value. This effect has been argued previously in the literature to provide a potential link to mass extinction phenomena on Earth. However, we focus on whether additional heat-flux from dark matter annihilations within the Martian core could have affected the decay of its geodynamo, and thus precipitated its magnetic field loss. We determine that Xenon1T limits on the WIMP nucleon cross-sections do not allow sufficient heating to significantly affect either Earth or Mars. We then use this to determine the local dark matter density and the density of a dark matter sub-halo that would support a significant effect given these limits. In addition, we have extended previous work on this topic by including resonant collisional effects, considering the impact of Xenon1T limits, and by considering possible effects on the evolution of the Martian geodynamo. We have lastly presented the possibility of Mars coming into contact with such a sub-halo.

Abstract

Over the past few years, X-/gamma-ray polarimetry has witnessed a boom with great results from missions like *POLAR*, *AstroSat*/CZTI, *IXPE* and *XPoSat*/POLIX. Furthermore, the numerous missions in the pipeline (e.g. *POLAR-2, COSI*, *LEAP*, *Daksha*, *eXTP*, etc.) that are dedicated or are capable of measuring X-/gamma-ray polarisation indicate coming-of-age for the field. Hence, going forward it is important to set standards for effective use of the data generated by current and future missions. We present *PolPy*, a universal tool that can be used for multi-instrument spectro-polarimetric analysis of data from current and future space-based X-/gamma-ray missions using common data format standards. We have defined the standards in consultation with several mission teams, and they are based on the well-established OGIP standards for spectroscopy. In its present format, *PolPy* utilises the Multi-Mission Maximum Likelihood (3ML) framework as the backend to fit spectro-polarimetric parameters; however, it can be easily extended to incorporate any other data analysis framework. The tool is instrument-agnostic and hence can be easily used for cross-instrument joint analysis if the data and response standards are followed. In this talk, I will present the common data and response standards which we have developed for X-/gamma-ray polarimetry, the *PolPy* package, and results of polarisation analysis using *PolPy* for two GRBs from *POLAR* and *AstroSat*/CZTI as an example.

Evolution of QPOs and other timing-spectral parameters of Swift J1727.8-1613 during the 2023 outburst observed with NICER and NuSTAR

Dr. Ramanshu P. Singh

Department of Physics, Prof. Rajendra Singh (Rajju Bhaiya) Institute of Physical Sciences for Study and Research, Veer Bahadur Singh Purvanchal University, Jaunpur, UP, India

Abstract

Several *NICER* and one *NuSTAR* observation have been analyzed for QPOs and other time-lag parameters of the newly discovered LMXB Swift J1727.8-1613 since it underwent into an outburst in mid-2023. Using *GHATS*, we observed the presence of type-C LFQPOs with varying centroid frequency in range 0.35-1.45 Hz. With the light-curves from NICER observation, hardness parameter has also been computed in 0.3-2.0 keV, 2.0-4.0 keV and 4.0-10.0 keV to trace the transition states. Further, we also analyzed the time-lag properties with *pyLag* and the results suggest that during the hard to soft transitioning state, the reverberation lags become wider and prominent at lower Fourier frequency. A model fit of const*tbabs*plabs(diskbb+relxillcp+cutoffpl) for the energy spectra in XSPEC suggests the inclination angle to be ~39.87 degree and spin to be ~0.978.

Adding Gamma-Ray Polarimetry to the Multi-Messenger Era

Merlin Kole[1,2], Nicolas Produit[1], Francesco Iacovelli[1], Michele Mancarella[3]

[1]University of Geneva. [2]University of New Hampshire. [3]INFN

Abstract

Many open questions remain regarding the emission from the high energy transient events known as Gamma-Ray Bursts (GRBs). Studies of the spectral and timing properties of both their bright prompt gamma-ray component as well as the longer lasting afterglow have taught us much about these extreme events. However, questions regarding the origin of the prompt gamma-rays as well as the structure of the jets in which they are thought to be emitted remain unanswered to this day. This can soon change thanks to the emergence of two novel measurement types: Gravitational Wave (GW) astronomy and high energy polarimetry. Here we explore how these two can complement one another. The polarization degree (PD) of the gamma-ray emission has long been thought to hold vital information regarding the emission mechanism. The polarization angle (PA), however, cannot be easily used as the orientation of the progenitor is not known. GW measurements can, in the near future, however measure this orientation. We will show here how information from GW measurements will improve model discrimination when combining it with the PD. Furthermore we will show how GW measurements will enable the PA to be used in this analysis. Furthermore, we will discus how, in addition, measurements with radio and optical can further complement such studies. Finally, the number of anticipated joint detections between current GW detectors and upcoming polarimetry missions such as POLAR-2, Daksha and LEAP will also be presented.

Relativistic viscous accretion flow model for BH-ULX sources with XMM–Newton observations

Dr. Santabrata Das

Indian Institute of technology Guwahati, Assam, India

Abstract

We develop a model formalism to study the structure of a relativistic, viscous, optically thin, advective accretion flow around a rotating black hole in presence of radiative coolings. We use this model to examine the physical parameters of four black hole Ultra-luminous X-ray sources (BH-ULXs), namely mass ($M_{\rm BH}$), spin ($a_{\rm k}$) and accretion rate (${\dot m}$), respectively. While doing this, we adopt a recently developed effective potential to mimic the spacetime geometry around the rotating black holes. We solve the governing equations to obtain the shock induced global accretion solutions in terms of ${\dot m}$ and viscosity parameter (α). Using shock properties, we compute the Quasi-periodic Oscillation (QPO) frequency ($\nu_{\rm QPO}$) of the post-shock matter pragmatically, when the shock front exhibits Quasi-periodic variations. We also calculate the bolometric luminosity ($L_{\rm bol}$) of the entire disc for these shock solutions. Utilizing $\nu_{\rm QPO}$ and $L_{\rm bol}$, we constrain BH-ULXs mass by varying their spin ($a_{\rm k}$) and accretion rate ($\dot m$). We find that NGC6946 X$-$1 and NGC5408 X$-$1 seem to accrete at sub-Eddington accretion rate provided their central sources are rapidly rotating, whereas IC342 X$-$1 and NGC1313 X$-$1 can accrete in sub/super-Eddington limit irrespective to their spin values.

Unrevealing pulsar radio beam shape.

Dr Krzysztof Maciesiak[1], Dr Rahul Basu[1], Prof Giorgi Melikidze[1,2], Dr Dipanjan Mitra[3,4]

[1]Janusz Gil Institute of Astronomy, University of Zielona Gora, Poland. [2]Evgeni Kharadze Georgian National Astrophysical Observatory, 0301 Abastumani, Georgia. [3]Janusz Gil Institute of Astronomy, University of Zielona Góra, Poland. [4]National Centre for Radio Astrophysics, Tata Institute of Fundamental Research, India

Abstract

Pulsar radio emission originates around 50-100 stellar radii above the surface, with the plasma responsible for the emission formed due to sparking in an inner acceleration region above the polar cap. The radio emission originates from the region of the open dipolar magnetic field lines that can be broadly considered as an emission beam. The most widely accepted model of the average emission beam consists of a central core component surrounded by two concentric rings of conal components. We have found the average emission beam to show evolution with pulsar parameters, particularly rate of the rotational energy loss, dE/dt. The traditional model seems to be more more applicable for older pulsars with lower dE/dt. Deviation from the above emission beam model occurs for younger pulsars, in higher dE/dt range. Interestingly other emission features like subpulse drifting and degree of polarisation also show dependence on dE/dt.

Our aim is to establish the average emission beam of the pulsar population using the publicly available databases from telescopes like MEERKAT, FAST, Parkes, etc. We have compiled the largest dataset of fully polarised average profiles (approx. 1800 pulsars), over a wide frequency range between 100 MHz and 5 GHz. These studies covers detailed characterisation of the average profile properties like profile classification, measurement of the profile as well as individual components widths, estimating the line-of-sight geometry, etc. This will enable us to estimate the average emission beam and study their evolution with different parameters like observing frequency, dE/dt, etc.

Studying the geometry of the emitting region in X-ray binaries using optical and X-ray polarimetry

Prof Juri Poutanen

University of Turku

Abstract

The launch of the Imaging X-ray Polarimetry Explorer (IXPE) in Dec 2021 opened a new era in the study of compact astrophysical objects. For unresolved sources, polarimetry is the only way to learn about the source geometry. In this talk, I will highlight the progress made thanks to IXPE in understanding the geometry and physics of emitting regions in accreting black holes and neutron stars. High-precision optical polarimetry complements these studies by adding information about the orientation of binary systems in the sky.

Radio Pulsars with gigahertz-peaked spectra

Jaroslaw Kijak

Janusz Gil Institute of Astronomy, the University of Zielona Gora, Poland

Abstract

The discovery of gigahertz-peaked spectra pulsars (GPS) revealed new aspects inthe field of pulsar spectra. Until today we know of more than 30 objects that show high-frequency turnover in the spectrum, between 0.5 and 2.0 GHz, and in the case of radiomagnetars the peak frequencies are above 2 GHz. The GPS phenomenon in pulsars is most likely a result of thermal free-free absorption of the pulsar flux in specialized environments along the line of sight. The appearance of the GPS in these pulsars is often related to the environments these objects reside in, such as pulsar wind nebulae (PWN), supernova remnant (SNR) nebulae, or H II regions.

The spectral nature in these objects were studied using the thermal free–free absorption model. The results of the fits were then used to estimate the physical properties of the absorbing electron gas: its density, temperature, and possible sizes of the absorber. In the summary we present and discuss the properties of the entire GPS pulsar population.

Wide-Band Observations of Pulsar Radio Emission

Jacob Cardinal Tremblay[1,2], Dr. Ramesh Karuppusamy[2], Prof. Dr. Michael Kramer[2]

[1]Max Planck Institute for Gravitational Physics. [2]Max Planck Institute for Radio Astronomy

Abstract

Pulsar radio emission is currently poorly understood, especially the wide-band coherent emission process. To arrive at a consistent theory which explains all observed emission features, other phenomena such as moding, nulling, and profile evolution must be examined in the wide-band context. For this purpose a radio receiver capable of receiving wide-band radio signals such as the Ultra-BroadBand receiver (UBB) is needed. The UBB is a novel receiver on the Effelsberg 100 meter radio telescope. The UBB is capable of detecting radio emission in the frequency ranges from 1.3 GHz to 6 GHz. This bandwidth is larger than typical receivers which is particularly interesting for studies which analyze properties that vary in frequency. Understanding the frequency dependent properties will not only help in understanding emission mechanisms of pulsars but can also lead to better timing precision for pulsar timing array experiments such as the European Pulsar Timing Array.

Quasi-two-dimenstionality of three-dimensional, magnetically dominated, decaying turbulence

Shreya Dwivedi[1,2], Chandranathan Anandavijayan[2], Pallavi Bhat[2]

[1]University of Wisconsin-Madison, Madison, WI 53706, USA. [2]International Centre for Theoretical Sciences, Tata Institute of Fundamental Research, Bangalore 560089, India

Abstract

Decaying magnetohydrodynamic (MHD) turbulence is important in various astrophysical contexts, including early universe magnetic fields, star formation, turbulence in galaxy clusters, magnetospheres and solar corona. Of particular interest are systems that are not driven by external agencies, i.e., are freely decaying and are magnetically dominated. An example in focus is the magnetic fields in the intergalactic medium, which are thought to be of primordial origin. Previously known in the nonhelical case, we show that magnetic reconnection is important also in the fully helical case and is likely the agent responsible for the inverse transfer of energy. Again, in the fully helical case, we find that there is a similarity in power law decay exponents in both 2.5D and 3D simulations. To understand this intriguing similarity, we investigate the possible quasi-two dimensionalization of the 3D system. We perform Minkowski functional analysis and find that the characteristic length scales of a typical magnetic structure in the system are widely different, suggesting the existence of local anisotropies. Finally, we provide a quasi-two-dimensional hierarchical merger model which recovers the relevant power law scaling. In the nonhelical case, we show that a helicity-based invariant cannot constrain the system, and the best candidate is still anastrophy or vector potential squared, which is consistent with the quasi-two-dimensionalization of the system. Studying the decay properties of these systems is vital to estimating the evolution of the strength and scale of cosmological magnetic fields. Thus, our findings could have far-reaching implications for the physics of the early universe.

Polarization signatures from blazars: A key observable for high energy emission mechanism

Ms Athira M Bharathan[1], Prof. CS Stalin[2], Dr Sunder Sahayanathan[3], Dr Blesson Mathew[1]

[1]CHRIST (Deemed to be University), Bangalore. [2]Indian Institute of Astrophysics, Bangalore.
[3]Bhabha Atomic Research Centre, Mumbai

Abstract

The distinctive low-energy hump observed in the broadband spectral energy distribution (SED) of blazars is a result of synchrotron radiation from relativistic particles in their jets. In the case of high synchrotron peaked (HSP) blazars, the observed X-ray emission falls within the high-energy tail of the synchrotron portion of the SED, allowing X-ray polarization measurements to provide constraints on the mechanisms governing particle acceleration in their jets. We present results on the X-ray polarization measurements of 1ES 1959+650, PKS 2155-304, Mrk 421 and 3C 454.3 based on observations carried out by the Imaging X-ray Polarimetry Explorer (IXPE). Also, we carried out model fits to the broad band SED of all the IXPE observed sources in order to understand the high energy emission processes. We found that sources with detectable X-ray polarization are all HSP blazars and their SEDs are well fit by leptonic models. Details of the results will be presented.

Multi-Screen scattering in Fast Radio Bursts

Mr Sachin Pradeep Etakkepravan Thulicheri

Max Planck Institute for Radio Astronomy

Abstract

Fast Radio Bursts (FRBs) are known for their scintillation and scattering phenomena, often attributed to multiple screens within the interstellar medium (ISM). These plasma screens, spanning from 1-100 AU in scale, cause multipath propagation and angular broadening of single pulses. When two screens appear "pointlike" to each other, they scintillate on both small and large scales, aiding in constraining scattering to FRB host galaxies.In this study, we use simulations to explore this regime, revealing that when one screen resolves the other, it quenches Milky Way scintillations.

We introduce a new theoretical framework to study multi-screen scattering of single pulses, considering the cosmological nature of FRBs and the screens involved. Our primary goal is to understand how pulses appear when screens resolve each other, allowing us to distinguish such systems.

Simulations show that changes in the scintillation pattern over time in the dynamic spectra of the pulse I(t,v) is the key. Moreover, we propose an updated formula for locating the host galaxy screen from the FRB source, giving insights into probing extragalactic ISM structures at AU scales. This approach also opens up avenues in calculating the velocities of such plasma screens, particularly when a sufficient number of bursts allows for the analysis of secondary spectra.

An intriguing prospect is the use of such screens as cosmic lenses to constrain emission region sizes from pulsars, FRBs, and other coherent emissions from neutron stars. Through simulation studies, we have devised a novel observational technique for this purpose.

Exploring possible effects of the dark sector on neutron stars

MSc Loreany Araujo[1], Prof. Dr. José Ademir Lima[2], Prof. Dr. German Lugones[3]

[1]IAG - University of São Paulo. [2]University of São Paulo. [3]Federal University of ABC

Abstract

The potential relationship between the baryonic and the dark sector of the universe is investigated in order to explore the possible effects of dark energy and dark matter in the structure of neutron stars. In our approach, a fraction of the dark components depend on the energy density of the baryonic matter. It is also discussed how the equation of state of dark energy, $p_{de} = \omega \rho_{de}$, affects the convergence of the mass-radius relation for constant and variable ω. As expected, the results are heavily dependent on the proportion of each component present in the interacting scenario. When the dark fluids interact and the amount of dark energy exceeds that of dark matter, there is an increase in mass and radius (although less apparent) in comparison to the baryonic case. This outcome is consistent with recent observations, which indicate increasingly higher masses.

Radio pulsars: a polarized perspective

Dr Lucy Oswald

University of Oxford

Abstract

Polarimetry of the radio emission from pulsars is a unique probe of the structure and evolution of the neutron star magnetosphere. In 1969, Radhakrishnan and Cooke proposed the "rotating vector model" as an explanation of the linear polarization angle properties of radio emission from the Vela pulsar, and in doing so opened up a wealth of possibility for mapping neutron star magnetic field geometries. With more polarimetric observations came the discovery of orthogonal polarization modes of pulsar radio emission, and further investigation, both observational and theoretical, revealed additional complexity in terms of orthogonal and non-orthogonal behaviour, circular polarization, and the relationship of these observations to the birefringent properties of the pulsar magnetosphere. With modern telescopes we can now probe pulsar radio polarimetry with greater sensitivity and frequency resolution than ever before, revealing insights into how the neutron star magnetic field structure evolves over its lifetime. In this talk, I will review the development of polarimetric studies of radio pulsars over the last half-century, explain what pulsar polarization reveals to us about the neutron star magnetosphere, and look forward to future possibilities in our new era of multi-wavelength polarimetry.

Spectro-timing Insights into the Neutron Star Low mass X-ray binary GX 340+0

Dr Yash Bhargava[1], Prof Sudip Bhattacharyya[1], Dr Jeroen Homan[2], Dr Mayukh Pahari[3]

[1]Tata Institute of Fundamental Research. [2]Eureka Scientific Inc. [3]Indian Institute of Technology Hyderabad

Abstract

Persistent neutron star low-mass X-ray binaries are a few of the enigmatic sources in the X-ray sky. These sources have been extensively observed with various X-ray missions and still are feebly understood due to their complex evolution. One of the subset of these sources includes Z-sources which trace a peculiar Z-shaped track on the Hardness-Intensity diagram. Z-sources are accrete close to the Eddington limit and trace the HID over a timescale of a few days. In this talk, I will discuss the spectral and timing properties of one of the prominent Z-source GX 340+0 which has been extensively observed with AstroSat. The wideband coverage with AstroSat has proved to be paramount to disentangling the spectral components and the fast time resolution and large effective area of LAXPC provide a unique timing view of the source to constrain the evolving components in the source. I will also discuss some prospects in the X-ray polarisation emission from this source in the context of the recently launched IXPE and XPoSat mission.

ACCRETION FLOW CHARACTERISTICS OF A BLACK HOLE CANDIDATE; MAXI J1535-571

mr Ambrose EZE[1,2], Prof Romanus EZE[3], Prof Augustine CHUKWUDE[3]

[1]Department of Physical and Geosciences, Faculty of Natural and Environmental Studies, Godfrey Okoye University, Enugu, Nigeria.. [2]Department of Physics with Electronics, College of Sciences, Evangel University, Akaeze, Ebonyi, Nigeria.. [3]Department of Physics and Astronomy, Faculty of Physical Sciences, University of Nigeria, Nsukka, Nigeria

Abstract

MAXI J1535-571 outburst was an episodic phase of enhanced dramatic changes/disruptions of the accretion disk. These lead to the ejection of optically thick (Keplerian) and optically thin (sub-keplerian) plasma/flow. The emergent thermal (multi-color black body) and non-thermal (power-law) X-radiations originate from the individual manifestations of components of the accretion flow. Hard X-rays are produced when soft photons are thermally or inverse comptonized by high-temperature electrons in the Compton cloud/post-shock region. The variations/fluctuations of components of the accretion flow create propagating oscillatory shocks/humps (Quasi-periodic oscillations) when the resonance condition is satisfied. Mass accretion rates are intrinsic properties of the accretion flow, and their variations/fluctuations seem to regulate other accretion flow characteristics. In this study, spectral analysis of MAXI J1535-571 data observed by the three X-ray missions (*MAXI/GSC, Swift/BAT*, and *NuSTAR*) during the hard-intermediate state was carried out using HEASoft version 6.26.1 and its software packages, and standard pipeline product of each detector. Spectral fittings/modeling data was done in XSPEC version 12.10.1f using a combination of selected XSPEC and TCAF models. These models gave a statistically acceptable fit with a reduced Chi-squared value of ≤ 1.0. The accretion flow characteristics were constrained, and their correlation with one another suggests that the saturation effect and variations/fluctuations of other accretion flow characteristics, intermittent/flickering behavior, and origin of photon index–QPO frequency (Γ–νQPO) relation are tied to the variations/fluctuations of the mass accretion flow rates.

Keywords; MAXI J1535-571, outburst evolution, hard X-rays, accretion flow characteristics; mass accretion rates.

A GPU-accelerated approach for realistic radiative cooling in black hole X-ray binary simulations

Mr Pedro Motta[1], Dr Rodrigo Nemmen[1,2]

[1]Universidade de São Paulo. [2]Stanford University

Abstract

Observational evidence of low-mass black hole X-ray binary systems (XRBs) reveals significant spectral changes over short periods, often associated with state transitions and accompanied by substantial alterations in the accretion flow. There is a great effort in simulating these systems using general relativistic magnetohydrodynamic (GRMHD) codes because the intricate interplay of magnetic topology, thermodynamics, and radiative processes imposes challenges. The cooling involved in these systems is not trivial to implement and can increase the computational cost considerably. In this paper, we propose an approach to address this challenge by incorporating a realistic cooling prescription, such as bremsstrahlung, synchrotron, and inverse Compton effects, in the GPU-accelerated code H-AMR leveraging the capabilities of GPU's texture memory. We observe a considerable speed enhancement, being approximately 10,000 times faster compared to resolving the equations on the fly. This method can be effective in the studying of the dynamic evolution of these systems, shedding light on the intricate processes involved.

Blazar physics through broadband radio polarization monitoring

Dr. Ioannis Myserlis[1,2], Prof. Alan Marscher[3], Dr. Svetlana Jorstad[3], Dr. Ramprasad Rao[4]

[1]Institut de Radioastronomie Milimétrique (IRAM). [2]Max-Planck-Institut für Radioastronomie.
[3]Boston University. [4]Center for Astrophysics | Harvard & Smithsonian

Abstract

Blazars, the subclass of jetted AGN with their outflow axes closely aligned to our line of sight, comprise one of the most energetic, long-lived phenomena in the Universe. They are among the main constituents of the high-energy sky, especially in gamma-rays and up to TeV energies, and one of possible sources of astrophysical neutrinos. The low-energy part of their SEDs is understood as incoherent synchrotron emission from their jets, which spans from radio to optical, UV or even X-rays and is both linearly and circularly polarized. On top of their persistent broadband emission, blazar jets often show pronounced variability across the electromagnetic spectrum with timescales from days/months down to minutes.

In this presentation, I will demonstrate our efforts to capture the complex phenomenology of blazar jets through dedicated multi-wavelength polarization monitoring programs using several large radio facilities operating at mm and cm wavelengths. Our observations, which cover two decades of frequency (2.6 GHz — 230 GHz), are used to follow the flux density and polarization variations of our blazar sample with a ~3-week cadence. The linear and circular polarization parameters and their variability are used to constrain the jet physical conditions, such as the magnetic field strength and topology, the particle density and the plasma composition and study their dynamics. In addition, we coordinate with multi-wavelength campaigns, including IXPE or MAGIC, to identify the high-energy emission mechanism of blazar jets based on the expected multi-band polarization characteristics.

ZWCL 1856.8 : A rare double radio relic system captured within NuSTAR and Chandra field of view

Dr. Aysegul Tumer

MIT Kavli Institute

Abstract

Observations of galaxy cluster mergers provide insights on the particle acceleration and heating mechanisms taking place within the intracluster medium. Mergers form shocks that propagate through the plasma, which result in shock/cold fronts in the X-ray, and radio halos and/or relics in the radio regime. The connection between these tracers and the mechanisms driving non-thermal processes, such as inverse Compton, are not well understood. ZWCL 1856.8 is one of the few known double radio relic systems that originate from nearly head-on collisions observed close to the plane of the sky. For the first time, we study NuSTAR and Chandra observations of such a system that enclose both relics within their field of view. The spectro-imaging analyses of the system provide evidence for a shock front coinciding with the northern relic (M = 1.8), and suggestions of inverse Compton emission at both relic sites.

[1]Universities Space Research Association (USRA). [2]IIT Bombay. [3]Tata Institute of Fundamental Research (TIFR). [4]Ashoka University. [5]University of Massachusetts. [6]Physical Research Laboratory. [7]Indian Centre for Space Physics

Abstract

The proposed Daksha mission comprises of a pair of highly sensitive space telescopes for detecting and characterizing high-energy transients, such as electromagnetic counterparts of gravitational wave events and gamma-ray bursts (GRBs). Along with spectral and timing analysis, Daksha can also undertake polarization studies of these transients, providing data crucial for understanding the source geometry and physical processes governing high-energy emission. Each Daksha satellite will have 340 pixelated cadmium zinc telluride (CZT) detectors arranged in a quasi-hemispherical configuration without any field-of-view collimation (open detectors). These CZT detectors are good polarimeters in the energy range 100 to 400 keV, and their ability to measure polarization has been successfully demonstrated by the cadmium zinc telluride imager onboard AstroSat. Here, we demonstrate the hard x-ray polarization measurement capabilities of Daksha and estimate the polarization measurement sensitivity (in terms of the minimum detectable polarization: MDP) using extensive simulations. We find that Daksha will have MDP of 30% for a fluence threshold of 10^{-4} erg cm^{-2} (in 10 to 1000 keV). We estimate that with this sensitivity, if GRBs are highly polarized, Daksha can measure the polarization of about five GRBs per year.

Electron scattering in an extended reprocessing envelope around optical Tidal Disruption Events

Dr. Giorgos Leloudas

DTU Space, Technical University of Denmark

Abstract

Tidal disruption events (TDEs) are panchromatic transient phenomena involving the violent disruption of stars by supermassive black holes, yet the precise origin of their optical luminosity is still debated. Here, we present insights from a sample of TDEs observed in polarized light, primarily with the VLT, incorporating both published (Leloudas et al. 2023) and new data. The analysis of both continuum and line polarization suggests an origin in electron scattering, indicating the presence of an extended reprocessing envelope encircling the accretion disk. Our modeling, utilizing the radiative transfer code POSSIS and different TDE models, including a super-Eddington accretion disk with outflows, produces predictions that align overall with the observed data. Observations of a rare relativistic TDE are consistent with a pole-on view, assuming axial symmetry.

Abstract

The Cadmium Zinc Telluride Imager (CZTI) on the AstroSat satellite exhibits strong sensitivity to Gamma Ray Bursts (GRBs), having detected nearly 600 of them, including approximately 50 that went unnoticed by other missions. Nonetheless, CZTI was not originally designed for GRB monitoring and lacks the capability to localise them. In this study, we introduce an innovative approach for GRB localisation based on the "shadows" created on the CZTI detector plane through the absorption and scattering caused by components and instruments on the satellite. By comparing the observed distribution of counts on the detector plane with simulated distributions using GEANT4 simulations with the AstroSat Mass Model, we can determine the sky coordinates of GRBs. Our localisation accuracy is characterized by a two-component model, featuring a narrow Gaussian component that encompasses nearly 50% probability of containing the source and a broader Gaussian component that accounts for the remaining spread. The localisation radius scales inversely with the number of counts detected. To validate this model, we apply the method to GRBs with known positions, and our findings show excellent agreement between the model and actual observations. This newfound capability enhances the CZTI's versatility in the exploration of GRBs and other fast high-energy transient events.

Exploring Energy-Dependent Temporal Variability in the Black Hole Binary GRS 1915+105

Ms Ruchika Dhaka

Indian institute of Technology Kanpur, India

Abstract

We conducted a comprehensive analysis of the black hole X-ray binary source GRS 1915+105 by simultaneously observing it with AstroSat and NICER in 2017. Our study employed a wide-range X-ray spectral-timing approach to gain a deeper understanding of the source's behaviour. The power density spectra from LAXPC and NICER revealed a broad prominent feature at 2 Hz and the component's fraction r.m.s increased with energy, while the time-lag was found to be soft. We found that the energy dependence of the fractional r.m.s and time-lag cannot be explained by variations of coronal spectral parameters only. Instead, a model where the coronal heating rate varies first and induces a change in the disk temperature and inner radius can explain the variation.

Where do neutron stars get their mass from?

Dr Marisa Geyer[1], Dr Vivek Krishnan[2], Dr Daniel Reardon[3], Dr Hagatiana Andrianomena[4]

[1]University of Cape Town. [2]Max Planck Institute fur Radioastronomie. [3]Swinburne University of Technology. [4]South African Radio Astronomy Observatory

Abstract

And how did the MeerKAT get its stripes? As in a children's book, observing intriguing phenomena such as large ranges in neutron star (NS) masses, is the easier part of a discovery. Understanding how such phenomena came to be, is far more ambiguous.

The Meertime Relativistic Binary programme running on the MeerKAT telescope in South Africa, is actively weighing neutron stars across many relativistic binary systems that contain a pulsating neutron star (or pulsar) and a white dwarf or main sequence companion. Optimal results through high precision pulsar timing are achieved by conducting dedicated orbital campaigns during superior conjunction at UHF and L-band frequencies.

I will highlight the results of studying a set of relativistic binaries and their implications for NS masses, including PSRs J1933-6211, J1614-2230 and J1902-5105. PSR J1902-5105, analysed as part of a student project collaboration, is the most massive NS yet found in MeerKAT data, and at the edge of challenging NS formation theories and the physics of their interiors.

PSR J1933-6211 is a relatively rare system where the analysis of both its kinematic and relativistic orbital parameters, allowed us to fully map its 3D orbital geometry and to obtain accurate mass estimates of both the pulsar and its companion. These measurements solved the mystery of the nature of PSR J1933-6211's companion, and in analogy to the PSR J1644-2230 binary strengthens the case for NS being massive not through accreting matter but *because, just like how the MeerKAT got its stripes, they were born that way.*

Polarization Measurements of the Gamma-Ray Burst Prompt emission with POLAR and prospects for POLAR-2

Hancheng Li, Merlin Kole, Nicolas de Angelis

University of Geneva

Abstract

Gamma-Ray Bursts (GRBs) are the most powerful electro-magnetic events in the Universe. Even after thousands of spectral measurements of these transient events, how and where the gamma-ray emission is produced remains poorly understood. Polarization measurements have long been theorized to be capable of breaking this stalemate. The POLAR detector was developed for this purpose. The data this dedicated gamma-ray polarimeter collected after its launch in 2016 allowed for polarization measurements of 14 GRBs in the 50-500 keV energy range. The results of POLAR indicate that the polarization level is low which is in agreement with the majority of the emission models. In addition, the data provides strong hints for temporal evolution of the polarization angle during the GRB, something which is not explained by any existing model. To probe the polarization properties more deeply the POLAR-2 project was initiated in 2019 and is currently planned to be launched towards the Chinese Space Station in 2027. The detector will have an effective area approximately 1 order of magnitude larger than POLAR and, as recently shown through calibration of the first prototype, is sensitive to polarization down to 30 keV. In addition, its effective area of over 2000 cm^2, access to an onboard GPU and a near real time communication to ground, will allow it to send detailed transient alerts within seconds. In this talk we will present a detailed overview of the results of POLAR along with a discussion on the impact POLAR-2 can have on the field.

Abstract

POLIX is the main scientific payload on XPoSat (X-ray Polarimeter Satellite), a dedicated X-ray polarimetry mission of the Indian Space Research Organisation, launched on 01st January 2024. Measuring polarization in celestial X-ray sources is a new frontier in X-ray astronomy, providing crucial insights into emission mechanisms in X-ray sources. POLIX is based on the anisotropic Thomson scattering of polarized X-rays from a low atomic mass scatterer (Beryllium) and their subsequent detection in X-ray proportional counters. The spinning of the satellite around the viewing axis of POLIX during source observations enables the polarization measurements by measuring the distribution of scattered X-ray photons. It is sensitive to X-ray polarization in the 8-30 keV range, which complements NASA's Imaging X-ray Polarimetry Explorer (IXPE), sensitive to polarization in the 2-8 keV energy range. POLIX is set to provide polarization measurements in this unexplored energy band, enabling in-depth investigations of astrophysical processes in neutron stars and black hole sources. The in-flight performance of the POLIX instrument and some early results will be presented.

Abstract

The origin of low-frequency Quasi-periodic Oscillations (QPOs) in black hole binaries remains a subject of intense debate, with a polarimetric perspective offering crucial insights. Utilizing the Hilbert-Huang transform method applied to Imaging X-ray Polarimetry Explorer (IXPE) observations of Swift J1727.8-1613 during its remarkable outburst, we conducted the first phase-resolved spectropolarimetric analysis on the QPO cycle. On average, the polarization degree (PD) and polarization angle (PA) were measured at 4.28% ± 0.20% and 1°.9 ± 1°.4, respectively. Furthermore, our phase-resolved analysis revealed a clear modulation of the photon index with the QPO phase, while no significant modulations in PD and PA were discernible. The observed polarization signatures present discrepancies with prevailing model expectations, which require further investigation to understand the underlying physics governing QPOs' origin.

Abstract

Recent observations by the Imaging X-ray Polarimetry Explorer (IXPE) provide a robust view of Her X-1, shedding light on its geometry and system precession. We present our latest analysis, integrating IXPE and NuSTAR data, to reevaluate Her X-1 geometric characteristics. Our time-resolved study reveals negative linear correlations for total flux versus polarization degree (PD) and pulse fraction versus PD. By fitting phase-resolved modulations of the Cyclotron Resonance Scattering Feature (CRSF) and polarization angle (PA), using respectively a simple dipole model and a Rotating Vector Model, we consistently constrain geometric parameters. Variations in χp (the position angle of the pulsar's spin axis) across Main-on observations hint at forced neutron star crust precession. A linear relationship between CRSF energy and PA suggests a dominant dipole magnetic field, with their modulations likely arising from viewing angle effects.

Testing the Rigidity Dependence of Galactic Cosmic Ray Intensity Variation using Algorithm Selected Forbush Decreases

Testing the Rigidity Dependence of Galactic Cosmic Ray Intensity Variation using Algorithm-Selected Forbush Decreases Sam Samuneti

University of Nigeria Nsukka

Abstract

Galactic cosmic rays (GCRs) are high energy particles originating from outside our solar system. In this study, we investigate the rigidity dependence of GCR intensity variations using algorithm-selected Forbush decrease (FD) data from daily averaged CR count stored at Apatity (APTY) and Haleakala (HLEA) neutron monitor (NM) stations between 1996 and 2008. The average FD magnitude respectively for APTY and HLEA are -8.04% and -4.00%. The magnitude of the mean values of the FDs reflects the different in their geomagnetic cutoff rigidities which is 0.57 GV and 13.30 GV respectively. We discover that the mean value of FD at APTY is greater than that at HLEA. This is thought to be caused by geomagnetic cutoff rigidities (R) at the two NM stations with R at HLEA being greater than that at APTY. The respective altitudes of APTY and HLEA are 177m and 3052m above sea level. It is predicted that NM with low R will record more FDs and larger sizes of CR flux intensity reductions than NM with higher values. This prediction is supported by the results in this submission. Additionally, the association between the FDs at the two stations and the corresponding solar wind disturbance parameters were tested using regression analysis which showed that interplanetary magnetic field (IMF), solar wind speed (SWS), disturbance storm time index (Dst) and geomagnetic index (ap) explain a portion of variability in CR flux intensity at the time of FD. All the results are statistically significant at 95% confidence level.

Neutron Star to Quark Star Conversion: The Catastrophic and Gradual Mechanism

Dr. Prasad R[1], Dr. Ritam Mallick[2]

[1]International Centre for Theoretical Sciences (ICTS-TIFR), Bangalore, India. [2]Indian Institute of Science Education and Research (IISER) Bhopal, India

Abstract

The existence of quark stars is an open problem in astrophysics, and the quest to find such stars has attained much focus in recent years. According to QCD theory, the extreme densities found in neutron star core could trigger a transition from hadronic matter to a more stable quark matter, leading to the formation of hybrid/quark stars. We explored both catastrophic and gradual conversion scenarios. Using general relativistic hydrodynamics simulations, we examined the shock-induced deconfinement, where a propagating shock wave triggers the conversion of the entire star within a mere 30-50 microseconds. The gravitational wave produced in this is a burst-type signal with frequency of about 100 kilohertz and holds promise for detection by future high-frequency detectors. The aftermath of deconfinement is 2-flavour quark matter (u,d) to 3-flavour quark matter (u,d,s) conversion and distinct emissions can originate from it. The time scale and energy budget available indicate that short gamma-ray bursts and fast radio bursts could arise in phase transition events. Further, we have addressed the spin-down driven phase transition scenario, a gradual conversion wherein magnetic braking drives neutron stars from their birth (Keplerian rotation) to later stages of life (slow spin). The rise in density during spin-down can lead to the formation of a quark core or the growth of an existing quark core. Persistent signals can emerge in this (braking index changes, GWs from excited oscillation modes, neutrino bursts). Detecting these multi-messenger signals and their sky localization may help find the quark/hybrid stars.

Towards an understanding of the pulsar radio emission mechanism.

Prof. Giorgi Melikidze[1,2], Dr. Dipanjan Mitra[3,1], Dr Rahul Basu[1], Dr Jaroslaw Kijak[1]

[1]Janusz Gil Institute of Astronomy, University of Zielona Góra, Zielona Góra, Poland. [2]Evgeni Kharadze Georgian National Astrophysical Observatory, Abastumani, Georgia. [3]National Centre for Radio Astrophysics, Tata Institute of Fundamental Research, Pune, India

Abstract

We present the results of recent pulsar observations that limit the nature of the possible radio emission mechanism. The study of the single pulse polarisation properties provides crucial insights into the features of the mechanism. The behaviour of the polarisation positional angle of time samples with high levels of linear polarisation reproduces the S-shaped curves that closely resemble the rotating vector model for the two eigenmodes of the relativistic electron-positron plasma: ordinary and extraordinary modes. The polarisations of these modes are mutually perpendicular. Moreover, certain observations showed that the detected polarisation vector must be directed either orthogonally or along the plane in which the curved dipole field lies. These observations greatly limit the number of possible mechanisms, as the successful mechanism should be sensitive to the direction of the curved magnetic field plane. This feature is an inherent property of the coherent curvature radiation mechanism.

We also address two essential requirements for any model of pulsar radio emission: the escape of radio waves from the pulsar magnetosphere and the level of circular polarisation. According to the standard model of the pulsar magnetosphere, the radio emission should detach from the plasma at heights less than 10% of the light cylinder radius, a phenomenon that is supported by observations. We show that within the partially screened gap model of the inner acceleration region, a nonstationary plasma flow is setup due to the sparking process. The nonstationary plasma flow naturally fulfils the observed properties of the radio emission without any additional assumptions.

Inferring Properties of Plasma in a Curved Spacetime

Daniel Palumbo

Black Hole Initiative at Harvard University

Abstract

Advances in sub-millimeter very-long baseline interferometry (VLBI) have brought the event horizons of supermassive black holes into focus. For the first time, we have direct access to synchrotron emission from plasma embedded in the strongly curved spacetime near a black hole. This region imposes additional structure on emission from magnetized plasma relating to deep symmetries of the spacetime. In this talk, I will outline how the Event Horizon Telescope infers basic properties of plasma from images, and how future VLBI observations can probe fundamental physics using the polarization of light. These techniques will allow space-VLBI missions like the Black Hole Explorer to separate light in the strongly lensed photon ring from the background emission. Lastly, I will detail fundamental limits on the inference of plasma properties under conditions of limited frequency access, viewing angles, polarization, and unknown electron distribution function. These results show that due to the strong lensing around black holes, degeneracies in plasma parameters are broken as multiple viewing angles on the same emitting material provide unique information to the observer.

Particle Acceleration in the Heliosphere and in Supernova Remnants

Larissa Ribeiro Magalhães, Camila Naomi Koshikumo, María Victoria del Valle, Reinaldo Santos de Lima

Instituto de Astronomia, Geofísica e Ciências Atmosféricas da Universidade de São Paulo (IAG-USP)

Abstract

Cosmic rays are charged particles that permeate astrophysical environments with energies much higher than the ambient thermal particles. The bulk of the galactic cosmic-ray protons and heavier nucleus, with energies up to PeV, are most probably energized in shocks resulting from supernova remnants (SNR) expansion in the interstellar medium, although the process is not yet fully understood. In the interplanetary medium, directly detected ions with energies in the tens of MeV range are correlated with shock fronts.

This research aims to develop a one-dimensional model to study the confinement and injection of energized protons in the heliosphere, using magnetohydrodynamic (MHD) simulations. Furthermore, this modified model, including a kinetic representation of the relativistic particles (Particle-In-Cell-MHD), was applied in SNR scenarios.

Our models were able to reproduce the evolution of shock events observed in the heliosphere, in accordance with previous MHD models in the literature, with the advantage of providing the energy distribution of the energetic particles, which can be used to better constrain the acceleration and diffusion processes. In the SNR case, our simulations produced the instabilities believed to regulate the self-confinement of the particles which affect the acceleration efficiency. In the future, we intend to apply it to construct non-thermal emission models of SNR that can be compared to observations.

This approach will contribute to the understanding of the cosmic ray acceleration process, as certain open questions, such as the development of instabilities near the shock, can be tested in the interplanetary medium, where direct observations are available.

Multi-wavelength observations of GRS 1915+105 during its unusual low state

Aarran Shaw

Butler University

Abstract

The black hole X-ray binary GRS 1915+105 has been in outburst since its 1992 and is famous for exhibiting a diverse range of accretion-related phenomena such as distinct variability classes, outflows such as jets and winds, and drastic changes in luminosity. In 2018, GRS 1915+105 began to transition to a new low-flux phase, where it has since remained. In 2023, we commenced an ambitious multi-wavelength observing campaign of GRS 1915+105 to study the temporal and spectral properties of the source during this phase. Observations spanned the electromagnetic spectrum from radio to hard X-rays, and utilized a variety of observatories including, but not limited to, JWST, ALMA, VLA and NuSTAR. We present here results from this campaign, focusing specifically on flux variations seen at X-ray energies and drawing comparisons with the variability seen at other wavelengths, in particular mid-infrared as observed by JWST.

Modelling of the irradiation of Knyahinya meteorite by galactic cosmic-ray protons

Doctor Patrik Čechvala, Associate Professor Robert Breier, Professor Jozef Masarik

Comenius University in Bratislava, Slovakia

Abstract

The extraterrestrial material in Solar system is exposed to the bombardment of cosmic-ray particles. Reaching sufficient energies, the interactions result in the generation of cosmogenic nuclides. Studying the production rates of different cosmogenic isotopes, it is possible to obtain valuable information about the exposition history or the original dimension of the extraterrestrial material. For this purpose, we have created model based on Monte Carlo simulation software Geant4 capable to simulate the irradiation of specific material, defined by user, by cosmic-ray particles. The model was tested in case of Knyahinya meteorite for which also experimental measurements of production rates of several cosmogenic nuclides are available. We would like to present the results of our model for chosen cosmogenic nuclides.

Highly collimated microquasar jets as efficient cosmic-ray sources

Dr. Gaston Escobar[1,2], Dr. Leonardo Pellizza[3]

[1]Physics and astronomy department Galileo Galilei, University of Padova, Italy. [2]Istituto Nazionale di Fisica Nucleare (INFN) - Padova, Italy. [3]Institute of Astronomy and Space Physics, University of Buenos Aires, Argentina

Abstract

Supernova remnants are currently believed to be the main sources from which Galactic cosmic rays originate. This scenario, however, fails to explain some of the features in the observed cosmic-ray spectrum, such as the spectral indices or the breaks (i.e. knee and ankle). Microquasars have been proposed as complementary candidates, because their non-thermal emission indicates the existence of efficient particle acceleration mechanisms in their jets. Some jets, such as that of SS 433, have been observed to have hadronic content. In these cases, the production of neutrons is an inescapable consequence of hadronic interactions. Given that neutrons cannot be magnetically confined, they escape from the jet and then decay, providing a way for charged particles to escape the system becoming cosmic rays. In this talk I will discuss neutron-driven cosmic-ray production in microquasar jets. I will show that this mechanism renders the most collimated, luminous, and compact microquasar jets as serious candidates for cosmic-ray sources. These jets provide a non-negligible proton cosmic-ray power, with a spectrum capable of producing the features observed at energies below the knee. I will also discuss the contribution of this mechanism to Galactic and extragalactic cosmic-ray production, especially at the Cosmic Dawn, when cosmic rays may have had an important role regarding the heating and reionization of the intergalactic medium.

Abstract Title: A series of NICER Thermonuclear Bursts from UCXB M15 XA series of NICER Thermonuclear Bursts from UCXB M15 X-2

María Alejandra Díaz[1,2], Prof. Juri Poutanen[1], Dr. Jari Kajava[3]

[1]University of Turku. [2]Nordic Optical Telescope. [3]European Space Astronomy Centre (ESAC)

Abstract

This poster provides the initial findings of a study focused on Type I X-ray bursts observed in the ultracompact X-ray binary 4U 2129+12, located in the globular cluster M15. Investigating ultracompact X-ray binaries (UCXBs) with hydrogen-poor companions offers valuable insights into accretion environments and neutron star atmospheres during bursts. Following the detection of an X-ray burst in September 2022, the Neutron Star Interior Composition Explorer (NICER) diligently monitored the 2022 outburst of this source. After analyzing the data from these subsequent observations, we have identified a total of 5 additional X-ray bursts. Performing time-resolved spectroscopy, we observed deviations from a blackbody in the spectra of all bursts. We significantly improved the fit by taking into account the enhanced persistent emission and have compared the results to those obtained through neutron star atmosphere models. Moreover, our examination of the fuel composition, indicating helium bursts, has refined our understanding of the companion's characteristics.

Detection of QPOs and other Timing-Spectral properties of GX 339-4 during the 2021 and 2023-2024 outbursts: a comparative study

Dr. Ramanshu P. Singh

Department of Physics, Prof. Rajendra Singh (Rajju Bhaiya) Institute of Physical Sciences for Study and Research, Veer Bahadur Singh Purvanchal University, Jaunpur UP India

Abstract

By undergoing an outburst at the end of the 2023, low mass x-ray binary GX 339-4 has again attracted astronomers' attention. Here, we present a comparative study on the timing-spectral properties of GX 339-4 during the 2021 and 2023-2024 outburst using NuSTAR and NICER observations. Using GHATS, we detected mutiple LFQPOs. QPOs with centroid ~0.08 Hz and ~0.35 are present in both cases, but we also detected a qpo with centroid 2.645 Hz in 2021 outburst while in 2023-2024 case, there is a QPO of centroid ~4.6 Hz with a signature of a harmonic at ~9.0 Hz. We have also calculated the hardness parameter using the NICER light-curves and also computed the time lag properties using pyLag to further correlated timing-spectral parameters at various phases of the outburst.

Unveiling the Most Promising Formation Channel of FRBs Using Local Universe Bursts

Dr Mohit Bhardwaj

Carnegie Mellon University

Abstract

The origin of fast radio bursts (FRBs) remains an enduring enigma in contemporary astronomy, even after 17 years since their serendipitous discovery. A plethora of models has been proposed to shed light on their origins, encompassing both cataclysmic and non-cataclysmic formation channels. Within the non-cataclysmic category, the debate persists on whether the majority of FRBs are promptly formed after the death of their progenitor main sequence star or arise from recycled compact objects. In this talk, I leverage currently available observational data to address three pivotal questions: (1) What are the prospects of detecting FRBs originating from proposed cataclysmic channels? (2) Is there a single dominant FRB formation channel, governing these enigmatic bursts? And if a dominant channel does exist, can it explain the observed diversity among FRB host galaxies and their local environments? To address these probing questions, I use a sample of two dozen local Universe FRBs ($z < 0.1$), many of which have been detected by the Canadian Hydrogen Intensity Mapping Experiment Fast Radio Burst (CHIME/FRB) Project. Our analysis provides compelling evidence that core collapse supernovae are likely the dominant formation channel of FRB sources. Additionally, I discuss our targeted search campaign of FRBs at the sites of pre-2005 Type II supernovae, which offers novel constraints on the age of the FRB sources. Finally, both of these findings carry considerable implications for multi-wavelength follow-up studies of FRBs, which I also discuss in this talk.

The CATCH Space Mission and Its Polarimetry Pathfinder

Dr. Qian-Qing Yin, Dr. Lian Tao, Dr. Xiangyang Wen, Dr. Zhengwei Li

Institute of High Energy Physics, Chinese Academy of Sciences

Abstract

The Chasing All Transients Constellation Hunters (CATCH) space mission, proposed in 2019, aims to bring about significant changes in X-ray astronomical observation by deploying an intelligent constellation of 126 microsatellites. These satellites, categorized into three types (Type-A, -B, and -C), will work in tandem to monitor the X-ray emissions of all-sky, multi-wavelength, multi-messenger transients. The primary objective of the mission is to provide a dynamic and comprehensive view of the universe through imaging, spectral, timing, and polarization measurements.

The mission will predominantly consist of 108 Type-A satellites, which will focus on monitoring the timing of transients detected by other survey telescopes. Subsequently, Type-B and -C satellites will conduct imaging-spectral-timing and polarization observations of the most intriguing transients based on the initial findings from Type-A satellites. The seamless coordination and collaboration of these satellites, facilitated by artificial intelligence, will establish a time-domain astronomical network for transients.

To validate the relevant technologies for Type-A satellites, the first pathfinder (CATCH-1) is expected to be launched in June 2024. This pathfinder will carry a Micro Pore Optics (MPO) and a 4-pixel Silicon Drift Detector (SDD) array. Following this, a polarimetry pathfinder (CATCH-2) for Type-C satellites will be developed and is expected to be launched around 2027. Equipped with a lightweight Wolter-I focusing mirror and a Gas Micro Plate Detector (GMPD) system, CATCH-2 will conduct rapid follow-up, high-sensitivity polarization measurements in the 2-10 keV energy range. It will also collaborate with other missions such as EP and SVOM to enhance its observational capabilities.

Metric type II radio bursts and associated space weather phenomena during solar cycle 24

Dr. Ramesh Chandra[1], Dr. Rositsa Miteva[2], Ms. Pooja Devi[1], Dr. Bendict Lawrance[3], Dr. Kostadinka Koleva[4]

[1]Department of Physics, DSB Campus, Kumaun University, Nainital, India. [2]Institute of Astronomy with National Astronomical Observatory, Sofia 1784, Bulgaria. [3]Department of Astronomy and Space Science, Kyung Hee University, 17104, Republic of Korea. [4]Space Research and Technology Institute, Bulgarian Academy of Sciences, Sofia 1113, Bulgaria

Abstract

We compile a catalog of metric type II radio bursts using Radio Solar Telescope Network (RSTN), to study the occurrence, associations, and properties of the emission and their parent solar activity phenomena. We analysed RSTN data in solar cycle 24 (2009–2019) from four worldwide stations: Learmonth, Sanvito, Sagamore Hills and Palehua. Through careful visual inspection, we have collected all major metric type II bursts detected in the range of 25–180 MHz. The relationships between these bursts and solar and their associated space weather (SW) phenomena, namely, solar flares (SFs), sunspot (SN) configurations, coronal mass ejections (CMEs), their interplanetary (IP) counterparts (ICMEs) and shocks, filaments, in situ detected particles and geomagnetic storms (GSs) are presented and discussed. The data of the associated phenomena is collected from various space-based satellites, ground-based observatories or public catalogs. We complement the m-II results with m+IP IIs where the IP IIs are identified from the Wind/WAVES spacecraft. Occurrence rates are calculated and presented as a function of the strength of the specific SW event type: higher rates are obtained with CMEs, SFs, and SN configurations, whereas a much weaker relationship is found with ICMEs, IP shocks, energetic particles, and GSs. The obtained relationships can be utilized in empirical or physics-based models for SW forecasting.

An investigation of the relation between CME cores and the near-surface prominence eruptions

Pooja Devi[1], Dr. Nat Gopalswamy[2], Dr. Seiji Yashiro[2,3], Dr. Sachiko Akiyama[2,3], Dr. Ramesh Chandra[1], Dr. Kostadinka Koleva[2,3,4]

[1]Department of Physics, DSB Campus, Kumaun University, Nainital 263 001, India. [2]NASA Goddard Space Flight Center, Greenbelt, MD 20771, USA. [3]The Catholic University of America, Washington, DC 20064, USA. [4]Space Research and Technology Institute, Bulgarian Academy of Sciences, Sofia, Bulgaria

Abstract

It is known that eruptive prominences are the near-surface manifestations of the core of the associated coronal mass ejections (CMEs). Previous studies have shown that the speed of the eruptive prominence is less than the associated CME core speed. This is because the prominences continue to accelerate before reaching the coronagraph field of view and hence the core speed is higher. However, we found a few exceptions in which the CME core speed is lower that the near-surface prominence speed: 11 May 2011, 01 October 2011, 7 June 2012, and 21 April 2014. We analysed these events using data of the Atmospheric Imaging Assembly (AIA) onboard the Solar Dynamics Observatory (SDO) together with coronagraph images from the Large Angle and Spectrometric Coronagraph (LASCO) onboard Solar and Heliospheric Observatory (SOHO) spacecraft. We discuss the situations that result in the higher prominence speed relative to the corresponding CME core speed.

Wave-particle interaction acceleration of proton and 3He/4He ions in impulsive flares with fractal turbulence reconnection model via 3D RHPIC-LBM simulations

Professor Boring Zhu

Yunnan Observatories of Chinese Academy of Sciences, Kunming, 650216, China. Center of Astronomical Mega-Science, Chinese Academy of Sciences, Beijing, 100012, China. State Key Laboratory of Space Weather, National Space Science Center, Chinese Academy of Sciences, Beijing, 100190,China. Earth and Planetary College & School of Astronomy and Space Science, University of Chinese Academy of Sciences, Beijing, 100049, China

Abstract

The high-energy solar energetic particles (SEPs) are the fundamental reason for SEPs-induced space weather disasters, especially for the GeV level flare/CME cases. However, due to the complex acceleration process (e.g., different species, different abundances, different isotopes, and different ionization), the acceleration mechanism and source & origin are still an open, challenging topic. Based on the statistical plasma treatment, this work investigates the wave-particle interaction acceleration mechanism on the supercomputer platform (e.g., Tianhe-series Homogeneous CPU and heterogeneous CPU-GPU systems) with relativistic hybrid particle-in-cell & lattice-boltzmann (RHPIC-LBM) code. The results show that wave-particle-interaction acceleration is a new independent turbulence acceleration mechanism that is different from the present turbulence acceleration mechanism (shock wave acceleration including 1st and 2nd fermi acceleration) and more efficient in high-energy level (e.g., GeV level) that shock wave acceleration mechanism.

Geomagnetic jerks observed in geomagnetic observatory data over Southern Africa between 2017 and 2023

Mr Sanele Khanyile

South African National Space Agency. University of KwaZulu Natal

Abstract

Geomagnetic jerks are jumps observed in the second derivative of the main magnetic field that occur on annual to decadal timescales. Understanding these jerks is crucial as they provide valuable insights into the complex dynamics of the Earth's outer liquid core. In this study, we investigate the occurrence of geomagnetic jerks in geomagnetic observatory data collected at southern African magnetic observatories, Hermanus (HER), Tsumeb (TSU), Hartebeesthoek (HBK) and Keetmanshoop (KMH) between 2017 and 2023. The observatory data was processed and analysed by retaining quiet night-time data recorded during quiet geomagnetic activities with the help of Kp, Dst and ring current RC indices. Results confirm the occurrence of 2018 and 2020 geomagnetic jerks in the region, and the recent 2021 jerk detected with V-shaped secular variation changes in X and Z components at all four observatories. The highest estimated 2021 jerk secular acceleration amplitudes in X and Z components were found at HBK, 12.7 nT/year^2 and 19. 1 nT/year^2, respectively. Notably, the global CHAOS-7 model aptly identifies this 2021 jerk in the Z component at all magnetic observatories in the region.

On the Magnetic Parameters of an Active Region Producing Flares and Confined Eruptions

Dr. Cristina Mandrini, Dr. Marcelo López-Fuentes, Dr. Mariano Poisson

Instituto de Astronomía y Física de Espacio - IAFE

Abstract

Active region (AR) NOAA 11476 produced a series of surge-type eruptions accompanied by GOES X-ray class M flares between 9 and 10 May 2012. Using force-free models and observations in several wavelengths, we studied the evolution of the eruptions and we associated them to the AR magnetic topology and suggest a reconnection scheme at their origin. The eruptions were due to the ejection of mini-filaments that were recurrently ejected and reformed at the polarity inversion line of a bipole that emerged in the middle of the positive main AR magnetic polarity. The bipole was observed to rotate for several tens of hours before the events. In this work, we analyze the evolution of a series of magnetic parameters for the full AR and the rotating bipole using the Helioseismic and Magnetic Imager (HMI) vector magnetograms. This analysis is combined with estimations of the injection of magnetic energy and helicity obtained using the Differential Affine Velocity Estimator for Vector Magnetograms (DAVE4VM) method. Our results let us conclude that the rotation of the bipole was the main driver providing the magnetic energy and helicity necessary for the mini-filament destabilizations and ejections.

Solar photospheric spectrum microvariability: Relations to magnetic activity and radial-velocity modulation

Prof Dainis Dravins[1], Dr. Hans-Günter Ludwig[2]

[1]Lund Observatory, Department of Physics, Division of Astrophysics, Lund University, SE-22100 Lund, Sweden. [2]Zentrum für Astronomie der Universität Heidelberg, Landessternwarte, Königstuhl, DE–69117 Heidelberg, Germany

Abstract

Searches for exoplanets around solar-type stars are limited by jittering of apparent radial velocities. To trace their origins, solar spectra were assembled from time-dependent 3D-hydrodynamics. Synthetic spectra were computed during numerous instances of the simulation sequences, producing movies of high-resolution solar spectral atlases.

The behavior was monitored for different classes of lines. The jittering scales to ~2 m/s for the full solar disk. Most photospheric lines vary in phase but amplitudes differ. Radial-velocity excursions are greater for stronger and for ionized lines, decreasing at longer wavelengths.

Extreme precision radial-velocity spectrometers enable extreme precision stellar spectroscopy. From three years of HARPS-N observations of the Sun-as-a-star, 1000 low-noise spectra were examined. Systematic line-strength variability largely shadows the solar-cycle evolution of Ca II H&K emission, but with much smaller amounts. Among iron lines, greatest amplitudes are for Fe II in the blue, while trends change sign among lines in the green Mg I triplet and between Balmer lines. Variations in the G-band core are greater than of the full G-band, in line with theoretical predictions. No variation is seen in the semi-forbidden Mg I 457 nm.

Microvariability in the photospheric spectrum thus measures something different than the Ca II H&K chromospheric index while still reflecting an influence from magnetic regions. A modelling with magnetic and nonmagnetic regions should be able to both reproduce solar-cycle changes in line-strengths and the ensuing changes in the apparent radial velocities of the Sun seen as a star.

Magnetic Detonation in Solar Flares

Andrei Sadovski[1], Alexey Struminsky[1], Irina Grigorieva[2]

[1]Space Research Institute, Moscow, Russia. [2]Main (Pulkovo) Astronomical Observatory of the Russian Academy of Sciences, St. Petersburg, Russia

Abstract

The emergence of solar flares and the development of coronal mass ejections (CMEs) and their relationships have been investigated for a very long time. However, the solution is very far from its completion. We developed a qualitative model for the emergence of CMEs as a result of multiple reconnection events and describe it as analogous to the process of detonation — magnetic detonation.

By such process we mean the propagation of multiple magnetic reconnection with a supersonic speed in eruptive flares and following acceleration of the CME. We found the limiting speeds of CME and proton acceleration time scale for CME.

Our model can be realized in in long flares in the presence of CMEs and particle acceleration but is not realized in short impulsive flares. We considered the possible expansion of the soft X-ray source, calculated its size and expansion speeds under the assumption that the plasma density in the source corresponds to the plasma frequency.

The Nature of the Solar Spicule Forest

Dr Piyali Chatterjee[1], Dr. Sahel Dey[2], Dr. Murthy O V S N[3], Prof Robertus Erdelyi[4], Dr. Jiajia Liu[5]

[1]Indian Institute of Astrophysics. [2]University of Newcastle, Newcastle, Australia. [3]Azim Premji University, Bengaluru. [4]University of Sheffield, Sheffield, UK. [5]University of Science and Technology of China

Abstract

At any given time, it is estimated that millions of spicules are present on the solar surface. We find an intriguing parallel between the simulated spicular forest in a solar-like atmosphere and the numerous jets of polymeric fluid in the laboratory when both are subjected to harmonic forcing. In our radiative (both 2D and 3D) MHD simulations with sub-surface convection, the solar surface oscillations are excited similarly to those harmonic vibrations. A forest of spicules are formed in our simulations with heights ranging between 6 and 20 Mm, bearing substantially closer resemblance to clusters of jets observed in the solar atmosphere. Taken together, the numerical simulations of the Sun and the laboratory fluid dynamics experiments provide insights into the mechanism underlying the ubiquity of jets. Our 3D numerical simulations further indicate an interesting relationship between spicules and what we refer to as "coronal swirling conduits" or CoSCos. In contrast to spicules that fall back to the solar chromosphere, the CoSCos form by drawing energy from the thermal and magnetic energy reservoir of the chromospheric plasma. These CoSCos have the potential to carry the rotational energy pulses further upward at Alfven speeds than the typical lengths of spicules seen in the Si IV emission lines even when spicules are falling sun-ward.

Solar Close Observation and Proximity Experiments (SCOPE) Mission Concept

Professor Jun Lin

Yunnnan Astronomical Observatories, Chinese Academy of Sciences

Abstract

The region close to the Sun is a totally unknown world to us, many important processes and phenomena occurring there are completely imperceptible on the Earth, and it is still an “uninhabited zone” for the deep space mission. This work is to introduce an unprecedented deep space mission that will enter the “uninhabited zone”, solving the puzzles that have challenged the solar physics society for around a century. These puzzles are related to the mechanisms for the solar eruption, detection of the coronal magnetic field, as well as the mechanism of the corona heating. The spacecraft will reach to the location closer to the Sun than the Parker Solar Probe would reach on an orbit of larger inclination to the ecliptic plane than the Solar Orbiter. The associated scientific goals include: 1. Entering the central structure of the energy release driving the solar eruption, performing in situ measurements of physical properties of the structure, and solving the problem of mechanisms of solar eruptions; 2. Acquiring the true thickness of the reconnecting current sheet connecting a coronal mass ejection to the associated solar flare, and renovating the classical theory and the physical scenario regarding the large-scale of magnetic reconnection; 3. Acquiring the coronal magnetic field via in situ measurement, obtaining unique evidence for identifying mechanisms of the corona heating, observing closely the polar magnetic field and plasma, revealing the role of the polar magnetic field and plasma in governing the global behavior of the solar activity.

Observations and 3D MHD simulations of turbulent reconnection within CME-flare current sheet

Xin Cheng

Nanjing University

Abstract

Magnetic reconnection is a fundamental physical process in various astrophysical, space, and laboratory environments. In solar physics, it is even believed to be a key mechanism to heat/accelerate plasmas and drive the eruption of large-scale magnetic field, giving rise to coronal mass ejections and flares, as well as solar energetic particles. High-cadence and high-resolution observations recently show that magnetic reconnection always presents an intermittency as characterised by the appearance of magnetic islands of different scales, which can be well understood in the framework of turbulent reconnection theory. In this talk, I will present observational evidence for turbulent reconnection within the current sheet in the wake of erupting coronal mass ejections and during a very tiny 3D magnetic null-point in the corona. We also implemented a 3D high-resolution MHD simulation of magnetic reconnection in a realistic flare configuration in order to explore the origin and property of turbulent reconnection, as well as its physical links to large-scale flare dynamics.

Toward Commissioning Solar Observations with MeerKAT: Opening a New Frontier in Solar Radio Physics

Dr. Devojyoti Kansabanik[1,2,3], Mr. Marcel Gouws[4], Prof. Divya Oberoi[3], Sarah Buchner[4], Dr. Surajit Mondal[5]

[1]Cooperative Programs for the Advancement of Earth System Science (CPAESS), Corporation for Atmospheric Research, Boulder, CO, USA. [2]Applied Physics Laboratory, Johns Hopkins university, LAUREL, MD, USA. [3]National Centre for Radio Astrophysics, Tata Institute of Fundamental Research, Pune, India. [4]South African Radio Astronomy Observatory. [5]Center for Solar Terrestrial Research, New Jersey Institute of Technology, Newark, NJ, USA

Abstract

Solar radio emissions provide several unique diagnostics tools of the solar corona, which are otherwise inaccessible. However, imaging the very dynamic coronal emissions spanning a large range of angular scales at radio wavelengths is extremely challenging. Due to large numbers of antennas, at GHz frequencies, MeerKAT radio telescope is possibly globally the best-suited instrument at present for providing high-fidelity spectroscopic snapshot solar images. At GHz frequencies, the Sun has a much higher flux-density than any other astronomical source in the sky. Hence, observing the Sun with sensitive radio telescopes like MeerKAT requires one to attenuate solar signals suitably for optimum operation of the instrument. We embarked on our voyage of MeerKAT solar observation using the sidelobes of the primary beam. The images show extremely good morphological similarities with the EUV images as well as the simulated radio images at MeerKAT frequencies demonstrating the high fidelity of these images. Although this approach was successful, it is naturally better to observe the Sun in the main lobe of the primary beam using suitable attenuation in the signal chain to keep the system in the linear regime. We have been working towards this and will present the current status of our efforts toward commissioning solar observations with the MeerKAT. Once commissioned, this will enable a host of novel studies, open the door to a large unexplored phase space with significant discovery potential, and also pave the way for solar science with the upcoming Square Kilometre Array-Mid telescope, for which MeerKAT is a precursor.

How have modern observations changed our understanding of small-scale bursts in the solar atmosphere?

Dr Chris Nelson

European Space Agency

Abstract

Small-scale bursts are prevalent throughout the solar atmosphere, from the photosphere to the corona. These events are often attributed to being the observational signatures of the physical process known as magnetic reconnection, the energetic restructuring of the local magnetic field from a high-energy state to a lower-energy state. As their name would suggest, the analysis of small-scale bursts relies heavily on high-resolution (in terms of both spatial and temporal capabilities) observations, with the definition of 'high-resolution' having evolved significantly with the development of larger and larger telescopes. Rapid advances in instrumentation over the past decade mean that we can now sample the solar atmosphere down to scales of tens of kilometres across a range of thermal windows. Combining these datasets together allows us to gain an insight into the heating and cooling process taking place in different regions of the solar atmosphere at any given time. In this talk, we will explore a range of small-scale bursts that have been identified in the transition region and corona of the solar atmosphere, as well as linkages between them. Specifically, this will include discussions of the new 'campfire' phenomena identified in coronal imaging data sampled by the Extreme Ultraviolet Imager onboard Solar Orbiter. The frequency and apparent temperatures of campfires make them potentially relevant as contributors to the long-standing open puzzle known as coronal heating. Finally, we will present a brief discussion about how data from the Daniel K. Inouye Solar Telescope will help to better understand small-scale bursts in the future,

Investigating Campfires and Their Relationship to Transition Region Explosive Events

Dr. Yajie Chen[1], Prof. Hardi Peter[1], Dr. Damien Przybylski[1], Dr. Hui Tian[2]

[1]Max Planck Institute for Solar System Research. [2]Peking University

Abstract

Recent observations by the Extreme Ultraviolet Imager (EUI) onboard Solar Orbiter have revealed prevalent small-scale transient brightenings in the quiet solar corona termed "campfires". To understand the generation mechanism of these coronal brightenings, we constructed a self-consistent and time-dependent quiet-Sun model extending from the upper convection zone to the lower corona using a realistic three-dimensional radiation magnetohydrodynamic simulation. From the model we have synthesized the coronal emission in the EUI 174 A passband. We identified several transient coronal brightenings similar to those in EUI observations (lifetime, size, aspect ratio, etc). By examining the magnetic field structures before and after the occurrence of brightenings, we concluded that these coronal brightenings are generated by component magnetic reconnection between interacting bundles of magnetic field lines or neighboring field lines within highly twisted flux ropes. These transient coronal brightenings may play an important role in the heating of the local coronal plasma. Furthermore, we synthesize spectral profiles of the Si IV 1394 A lines from the model. All seven campfires in our model show enhanced Si IV emissions, and most of them exhibit non-Gaussian Si IV line profiles. On the other hand, many explosive events do not show any coronal signature in the synthesized EUI 174 A images. Therefore, campfires often occur together with transition region explosive events, but the released energy around most explosive events is insufficient to heat the plasma there to 1 MK.

The Power of Ground-based Coronagraphs

Sarah Gibson, Ben Berkey, Joan Burkepile, Giuliana de Toma, Alfred de Wijn, Michael Galloy, Holly Gilbert, Maurice Wilson

NCAR/HAO

Abstract

For decades, we have observed the low and middle corona with instruments from the Mauna Loa Solar Observatory, including the white light K-Coronagraph (K-Cor) and the Coronal Multichannel Polarimeter (CoMP) and Upgraded CoMP (UCoMP). These instruments have demonstrated the crucial benefits of coronagraphs with small occulting disks (relative to space-based coronagraphs) for characterizing the nature of coronal mass ejection (CME) source regions and providing early warnings of CME launches, an advantage compounded by the extremely high cadence/latency possible with ground-based observations. In this presentation, we will discuss the particular advantages of ground-based white-light and visible-infrared coronagraphs, which enable unique measurements of coronal mass and magnetism. We will discuss the advantages gained by global networks of coronagraphs and by large aperture coronagraphs (e.g., COSMO), and the critical importance of global (full-Sun) synoptic observations for studying the processes of magnetic storage and release in the solar corona.

Solar Radio Type V Burst: Scattering, Trapping, and Emission Process of a Dense Electron Beam

Professor Arnold Benz[1,2], Clemens Huber[3], Vincenzo Timmel[2], Christian Monstein[4]

[1]Institute for Particle Physics and Astrophysics, ETH Zurich, 8093 Zurich, Switzerland. [2]University of Applied Sciences and Arts Northwestern Switzerland, FHNW, I4ds, 5210 Windisch, Switzerland. [3]Gymnasium Rämibühl, Rämistrasse 56, 8001 Zurich, Switzerland. [4]IRSOL Istituto Ricerche Solari "Aldo e Cele Dacco", Universita della Svizzera italiana, via Patocchi 57, 6605 Locarno, Switzerland

Abstract

Solar type V radio bursts are associated with type III bursts. Several processes have been proposed to interpret the association, the electron velocity distribution, and the emission. We present the observation of a unique type V event observed by e-CALLISTO on 2121/05/07. The type V radio emission follows a group of U bursts. Its polarisation is opposite to the type III burst and its front edge has a U-shape. The observations conform to a scenario where a dense electron beam first saturates its two-stream instability (causing type III emission) and then becomes unstable to another instability, such as the electron firehose instability. This second instability scatters some beam electrons into velocities perpendicular to the magnetic field and produces a trapped distribution prone to electron cyclotron masering (ECM). A reduction in beaming is predicted for electron beams continuing to interplanetary space, observable for Parker Probe and Solar Orbiter.

The Origins of Coronal Mass Ejections and their Initial Stages: An ObservationalAccount

Prof. SPIROS PATSOURAKOS

Department of Physics, University of Ioannina, Greece

Abstract

The chance discovery of Coronal Mass Ejections (CMEs) in the early 70's turned out to be a major milestone in solar physics and the Sun-Earth and Sun-stellar connections. Our understanding of these fascinating and important phenomena keeps making important strides thanks to advances in both observational and modelling/theory fronts. With this presentation, we attempt to supply an observational account of recent advances and challenges about the origins and initial stages of CMEs. We will feature topics including: 1) the pre-eruptive magnetic configuration of CMEs; 2) CME evolution in the low corona; 3) the search of physical parameters/regimes with the potential to identify regions which could spawn CMEs. We will conclude by discussing outstanding open questions in CME research and how observations from existing and upcoming instrumentation may accommodate them.

Preliminary prediction of solar active region evolution using deep learning

Dr. Harim Lee[1], Dr. Eunsu Park[2], Dr. Yong-Jae Moon[1], Dr. Jihyeon Son[1]

[1]Kyung Hee University. [2]Korea Astronomy and Space Science Institute

Abstract

Solar active regions are important for solar physics research and have been used as an input for various space weather forecasting models. In this study, we are developing a prediction model for solar active region evolution using video prediction methods based on deep learning. For the dataset, we use magnetograms observed by Solar Dynamics Observatory (SDO) / Helioseismic and Magnetic Imager (HMI). For magnetograms we use the Cylindrical Equal Area (CEA) projected HMI Active Region Patches (HARPs) data provided by JSOC, which have an advantage that they have the same area per pixel, without any additional data pre-processing. We consider 720 HARPs within ±30 degrees of the solar central meridian and with HARPs of 512x512 size from May 2010 to May 2023 (about 1 million images at 12 minute intervals). For the deep learning models, we consider several spatiotemporal prediction models, such as ConvLSTM and Top-tier video prediction models. Our models are designed to predict the change of active regions over the next 24 hours. Our study is a new attempt to predict the evolution of solar active regions using deep learning and is meaningful in providing useful information on solar activity forecasts.

Solar radius variability over the solar cycle.

Dr Jan Louis Raath, Dr Martin Snow

South African National Space Agency

Abstract

We study the variability of the solar radius between 2017 and the present. This period of time includes solar activity levels ranging from minimum to approximately maximum conditions. We make use of solar spectral irradiance observations, as measured by the GOES-16 satellite in the ultraviolet and visible spectral ranges. The observations are made during lunar transits of the Sun, as observed from the spacecraft. During these transits, the ratio of the solar to lunar radius can be obtained and, since the lunar radius is well known, we can obtain an absolute value for the solar radius. By obtaining such values for each of the lunar transits, we can achieve valuable insights as to the variability of the solar radius on the time scale of the solar activity cycle.

Space Weather at Mars: A Solar Cycle of Space Radiation Measurements on the Surface of Mars with RAD on the Mars Science Laboratory

Dr. Donald M. Hassler[1], Dr. Cary Zeitlin[2], Dr. Bent Ehresmann[1], Dr. Robert Wimmer-Schweingruber[3]

[1]Southwest Research Institute. [2]NASA. [3]CAU/Kiel

Abstract

The Radiation Assessment Detector (RAD) on the Mars Rover Curiosity has been effectively serving as a space weather monitor on the surface of Mars since Curiosity landed on the red planet in 2012. RAD has measured the impact of more than a dozen solar storms, with the frequency of events increasing as the Sun approaches solar maximum. Two recent relatively large events (Sept. 10, 2017 and Oct. 28, 2021) were observed as Ground Level Events (GLEs) at both Earth and Mars, separated by 180 degrees in longitude. We will discuss these events and their implications for space weather predictions, as well as the need for heliosphere-wide space weather monitoring to support future human exploration to Mars and beyond.

Solar Cycle Prediction at NOAA's Space Weather Prediction Center

Mark Miesch

Cooperative Institute for Research in the Environmental Sciences, Univ. Colorado, Boulder, CO, USA

Abstract

In 2019 the US National Oceanic and Atmospheric Administration (NOAA), the National Aeronautics and Space Administration (NASA) and the International Space Environment Services (ISES) convened an international panel to predict the amplitude and timing of Solar Cycle 25. We now believe that Solar Cycle 25 is likely to be stronger and to peak sooner than predicted in 2019. In order to address this, NOAA's Space Weather Prediction Center (SWPC) has deployed a new experimental product for predicting the amplitude and timing of Solar Cycle 25. This product remains faithful to the NOAA/NASA/ISES panel but provides more reliable practical guidance for SWPC customers. It is based on nonlinear curve fits applied to monthly sunspot and F10.7 cm radio flux observations and is updated every month as new observations become available. Error bars are estimated by applying the same method at the same point in past cycles and computing residuals. As of February 2024 the new method predicts a maximum sunspot number of 136-169 to occur sometime between February 2024 and February 2025. This prediction method provides a robust benchmark by which other more sophisticated solar cycle prediction methods can be evaluated. In this presentation I will describe the experimental product, including its methodology and validation, and I will demonstrate how to access it on NOAA/SWPC's new Space Weather Prediction Testbed website. I will also review the motivation and history of SWPC's solar cycle prediction products and describe a preliminary forecast method for Solar Cycle 26.

Analysis of the Occurrence of the First Most Intense Geomagnetic Storm (G4) to Hit the Earth in Solar Cycle 25

Dr Hammed Adeniyi Lawal[1], Mr Muhammed Itopa Mukhtar[2,3]

[1]Air Force Institute of Technology, Kaduna. [2]Kaduna State University, Kaduna; Nigeria. [3]Air Force Institute of Technology, Kaduna; Nigeria

Abstract

A study of the occurrence of the first intense Geomagnetic storm (G4) to hit the Earth since the start of the Solar Cycle 25 is carried out. This study analyzed the Geomagnetic Storm that occurred between the 28th of October and the 7th of November 2021. The values of the Disturbance storm time (Dst) index of the storm reach -115 nT (G4) which occurred on the 4th of November at 1300UT. The storm is the first intense magnetic storm that occurred in the solar cycle 25. It is also a multiple-step storm with moderate two-step storm occurrence which occurred on the 5th and 6th of November at 1500UT and 0600UT respectively towards the recovery phase after the intense storm. The interplanetary magnetic field (IMF)Bz (nT) during these storm events decreases. Our analysis shows that the rise in solar wind speed, temperature and the enhancement of pressure plays a significant role in the occurrence of the first intense Geomagnetic storm of Solar Cycle 25

Pixel-to-pixel translation of SDO/AIA EUV images for DEMs by deep learning

Eunsu Park[1], Harim Lee[2], Yong-Jae Moon[2], Seonghwan Choi[1]

[1]Korea Astronomy and Space Science Institute. [2]Kyung Hee University

Abstract

We suggest a pixel-to-pixel image translation method among similar types of filtergrams such as solar extreme-ultraviolet (EUV) images. For this, we consider a deep-learning model based on a fully connected network in which all pixels of solar EUV images are independent of one another. We use six-EUV-channel data from the Atmospheric Imaging Assembly (AIA) on board the Solar Dynamics Observatory (SDO), of which three channels (17.1, 19.3, and 21.1 nm) are used as the input data and the remaining three channels (9.4, 13.1, and 33.5 nm) as the target data. We apply our model to representative solar structures (coronal loops inside of the solar disk and above the limb, coronal bright point, and coronal hole) in SDO/AIA data and then determine differential emission measures (DEMs). Our results from this study are as follows. First, our model generates three EUV channels (9.4, 13.1, and 33.5 nm) with average correlation coefficient values of 0.78, 0.89, and 0.85, respectively. Second, our model generates the solar EUV data with no boundary effects and clearer identification of small structures when compared to a convolutional neural network–based deep-learning model. Third, the estimated DEMs from AI- generated data by our model are consistent with those using only SDO/AIA channel data. Fourth, for a region in the coronal hole, the estimated DEMs from AI-generated data by our model are more consistent with those from the 50 frames stacked SDO/AIA data than those from the single-frame SDO/AIA data.

Solar Coronal Jets and Jet-like Features: Their Nature, and Their Possible Implications for the Solar Wind

Dr. Alphonse Sterling[1], Dr. Ronald Moore[2,1], Dr. Navdeep Panesar[3,4]

[1]NASA/MSFC. [2]University of Alabama Huntsville. [3]Bay Area Environmental Research Institute. [4]Lockheed Martin Solar and Astrophysics Laboratory

Abstract

The Sun's hot (~1 MK) outer atmosphere, the corona, can be seen from the ground in its full glory for only a few minutes during total solar eclipses. From space, however, it can be seen continuously with EUV and X-ray telescopes. In recent decades, such high-resolution (a few arcseconds or less) and high-time-cadence (a few minutes down to seconds) observations have shown the corona to be dynamic on the time scale of a few minutes. Solar "coronal jets" are one such prominent dynamic feature: They resemble long narrow geysers that shoot out from near the Sun's surface and reach far out into the corona, sometimes extending out to about 50,000 km with a width of only about 10,000 km or less, over a lifetime of tens of minutes. Recent observations indicate that coronal jets usually (if not always) result from eruptions near the solar surface of “minifilaments.” These minifilaments are small-scale versions (size ~10,000 km) of typical large-scale filaments (~30,000 --- 100,000 km) that have long been known to erupt and produce typical solar flares and coronal mass ejections (CMEs). Smaller scale "jet-like features" in the solar atmosphere, such as "jetlets," and spicules, are even more common than jets, and might work the same way as jets. Small-scale erupting minifilaments (or more specifically, the erupting small-scale magnetic flux ropes that often carry chromospheric-temperature minifilament material) that produce these events plausibly could power the solar wind and evolve to form the magnetic "switchbacks" commonly observed by the Parker Solar Probe satellite.

An expansion-driven Alfvén wave dynamo generates mean magnetic field in the solar wind

Prof Stuart Bale

University of California, Berkeley

Abstract

The global solar magnetic field arises from dynamo processes associated with convective plasma motion in the outer envelope of the Sun. The solar wind, escaping from coronal holes, entrains this magnetic field and transports it out into the heliosphere to become the global heliospheric magnetic field (HMF). The HMF is predominantly radial in the inner heliosphere and becomes structured as a large-scale Archimedean spiral (the so-called Parker Spiral) at larger distances in the Ecliptic plane. The HMF is also punctuated by transient shocks and pileup where fast and slow wind streams meet (corotating interaction regions). Conservation of magnetic flux requires that the radial component of the HMF scale as $1/r^2$ becoming accordingly weaker at high altitudes. Here we report in situ measurements demonstrating that the radial component and magnitude of the global HMF *increase* beyond the expectations of flux conservation over a range of altitudes in the inner heliosphere. This growth of the mean field is associated with the generation and evolution of large-amplitude $\delta B/B \sim 1$ spherically-polarized Alfvén waves (termed 'switchbacks'). Alfvén waves generated at low altitudes are amplified by combined wind expansion and wave action conservation to grow to large amplitudes. As wave growth saturates and plasma motions begin to dominate, the Alfvén waves evolve to MHD turbulence and the underlying HMF is amplified. Our results may address, in part, the 'missing flux' problem.

The JAXA's next solar mission SOLAR-C: mission status update

Prof. Toshifumi Shimizu

ISAS/JAXA

Abstract

As a next observatory on orbit for high resolution solar physics, Japan Aerospace eXploration Agency (JAXA) has launched the SOLAR-C project team toward a launch target in Japanese fiscal year 2028. The SOLAR-C mission is a JAXA international mission in collaboration with US and European countries. High resolution observations allow us to investigate MHD fundamental processes acting in solar outer atmosphere and to take great contributions to revealing the mechanisms responsible for the heating of the upper atmosphere and explosions there. New imaging spectroscopic observations in EUV are eagerly awaited as the highest priority in latter half of 2020s. The SOLAR-C will carry the EUV high-throughput Spectroscopic Telescope (EUVST), which is a state-of-the-art EUV imaging spectrometer with slit-jaw imaging system, that will, for the first time, carry out simultaneous observations of the solar atmosphere from the photosphere/chromosphere up to the corona with seamless temperature coverage, high spatial resolution (0.4"), and with high throughput for achieving 0.5 sec high temporal cadence. The Phase-B development for the EUVST is on-going and preliminary design review (PDR) will be completed by the time of the IAU GA symposium. The EUVST observations are expected to be deeply coordinated with NASA's MUSE mission, other space missions, and ground-based facilities, to enhance synergies that are expected from such coordinated observations. This presentation will report on the latest status of the mission to be shared with the meeting participants, with reviewing scientific capabilities and expected performance of the mission.

The Cosmic-on-Air citizen science project: flight-based observations of cosmic rays and solar flares

Prof Andy Buffler[1], Dr Carine Briand[2], Dr Tanya Hutton[1], Dr Gael Patton[3], Dr Francois Trompier[4]

[1]University of Cape Town. [2]Observatoire de Paris-PSL. [3]Icohup. [4]Institut de Radioprotection et de Sûreté Nucléaire

Abstract

The Earth is constantly being bombarded by energetic charged particles associated with both Galactic Cosmic Rays (GCRs) and Solar Particle Events (SPEs). The Earth's atmosphere and magnetic field provide a natural barrier to this radiation at ground level, but this protection is less effective with increasing altitude which impacts the radiation exposure of aircraft crew and passengers. For example, the dose rate at a typical aircraft cruising altitude of 11 km is about 10 micro-sieverts per hour, approximately two orders of magnitude higher than at sea level.

Dosimetry of aircrew is routinely achieved using numerical approaches validated by measurements made on board aircraft. However, in cases of randomly occurring solar eruptive phenomena, which can produce a burst of sufficiently energetic SEPs to be classified as a Ground Level Event (GLE), the dose rates at flight altitudes can be significantly increased. Current dosimetry models for GLEs cannot be easily validated due to the very few on-board measurements during such phenomena.

We present Cosmic-on-Air, a citizen science project, which aims to increase coverage of measurements of cosmic radiation on board aircraft in the search of solar eruptive phenomena. A series of low-cost, compact, and connected radiation monitors are available to the public for purchase, and the data measured during flights are uploaded to an open data repository for analysis. We discuss the science that is possible from these measurements, the impact on dosimetry models for aircrew, the development of next-generation detectors, and the science outreach which is catalysed through the program.

Solar small-scale magnetic fields and their effect on convection and activity

Matthias Rempel

NSF NCAR, High Altitude Observatory

Abstract

The Sun is a unique star in the sense that we can observe it at high resolution and study phenomena with a detail that is hidden in stellar observations. This applies specifically to small-scale magnetic fields that are organized on the stellar surface on scales of granulation and smaller. Observations have shown that these small-scale magnetic fields are ubiquitous in the solar atmosphere and appear to be mostly independent of the solar sunspot cycle, which provides strong support for a small-scale magnetic dynamo. In this talk I will provide an overview of developments over the past 10-20 years. Recent research has clarified the role of the magnetic Prandtl number for small-scale dynamo action during both kinematic and saturated phase of dynamo operation and demonstrated that the low Pm found in stellar convection zones does not prevent small-scale dynamo operation as thought earlier. Simulations of strongly stratified convection point to a small-scale dynamo that operates over a wide range of scales in the solar convection zone and produces a magnetic field of a large enough strength to have a dynamical impact on convection. I summarize findings from simulations in terms of spatial distribution of magnetic energy, anisotropy of magnetic field throughout the atmosphere, effects on irradiance, the energetics of the dynamo and overall contributions to heating of the quiet Sun solar corona. Recent findings indicate that the small-scale dynamo may also influence convective power on the largest scales and play a critical role in establishing the solar differential rotation.

Heliopsheric and Magnetospheric modulation of cosmic rays during the St. Patrick day storms of 2013 and 2015.

Dr Kingsley Okpala

Department of Physics and Astronomy, University of Nigeria, Nsukka, Enugu State, Nigeria

Abstract

The heliospheric and magnetospheric conditions from cosmic ray observations during the March 16-17, 2013 storm and March 17, 2015 super storm is studied. Data from the OMNI database and cosmic ray data measurements at the Geostationary Operational Environmental Satellite (GOES) and from global network of neutron monitors were employed. The interplanetary magnetic field (IMF), proton density, coronal mass (CME) speed and the, heliospheric current sheet (HCS) were investigated. The magnetospheric conditions were deduced from the disturbance storm time index. The principal component analysis from the scores of the PC1 of the Cosmic rays during these storms reveal that the IMF and HCS accounts for the greatest variance (>74%) of the cosmic rays during the storms. Both storms reveal a small but significant contribution from the ring current during the main phase of the storm. These results have important implications for the present understanding of the modulation of cosmic rays during energetic events in the heliosphere.

Magnetic Loop breakout during a X5.0 Class Flare

Xiaofan Zhang[1,2], Prof. Guiping Zhou[1,2]

[1]The National Astronomical Observatories of the Chinese Academy of Sciences. [2]University of Chinese Academy of Sciences

Abstract

We newly report a magnetic loop breakout process during a GOES X5.0 class flare initiating at 21:36 UT on December 31, 2023. The breakout of the magnetic loop was triggered by the eruption of a magnetic flux rope (MFR) below, which was situated above the polarity inversion line (PIL) of AR 13536 with two footpoints located in the positive and negative polarities, respectively. Especially, both the studied magnetic loop and the MFR below share their west footpoints in the same positive magnetic patch of a sunspot with strong magnetic fields. The MFR showed instability since 20:47 UT that manifested as intermittent brightenings of its two footpoints based on EUV observations from the Solar Dynamics Observatory/Atmospheric Imaging Assembly (SDO/AIA). The MFR was identified as a high-temperature magnetic-channel structure in 131 Å. It erupted with two flare ribbons along the PIL. Its ejecting material first interacted with the nearest magnetic loops, but caused none of topologic changes. When the ejecting MFR kept reaching the studied magnetic loop that shared the same west magnetic footpoints, this magnetic loop occurred magnetic breakout phenomenon. An associated EUV wave was observed to propagate through a coronal hole nearby at the southeast. The intensity variation of the coronal hole was analyzed to relate to the dynamic process of the EUV wave. It discusses that the strong magnetic interactions in the PIL near the sunspot destabilized the MFR. The eruption of the MFR modified the magnetic fields of its west footpoint, which was also beared the instability of the studied magnetic loop. This should be the reason that the magnetic loop can happen magnetic breakout. Our findings provide insights into the new physical mechanisms of solar eruptions by uncovering the magnetic breakout process of a magnetic loop that was triggered by the ejecting MFR.

A multi-wavelength investigation into the photospheric effects of a solar flare on 1 July 2012 using Swedish Solar Telescope observations

Dr Ruhann Steyn[1], Dr Gert Botha[2], Prof Eamon Scullion[2]

[1]North-West University. [2]Northumbria University

Abstract

The solar flare event of 1 July 2012 13:08 UTC was observed in multiple wavelengths by the Swedish Solar Telescope (SST), providing information about the state of the photosphere, chromosphere and corona. In this study, focus is placed on the changes in sheared photospheric flow pre and post flare. Two pores and several bright points inside the flow pattern are tracked using the Local Correlation Tracking software package YAFTA. The border between two counter flows and the location of a polarity inversion line are identified, while the distance between two pores over time is monitored for the changes in magnetic field line tension. The velocity flow vectors show the degree of shearing before and after the solar flare and the Poynting flux quantifies the magnetic energy evolution before and after the flare. The SST results are combined with results from the Solar Dynamics Observatory (SDO), the Geostationary Orbital Environmental Satellite (GOES) and the FERMI Gamma-Ray Space Telescope providing a multi-wavelength evolution of this event.

Investigating the relationship between photospheric differential rotation and sunspot area using the Solar Observing Optical Network and terrestrial solar observations from the North-West University solar telescope

Ms Calmay Lee, Dr Ruhann Steyn

North-West University

Abstract

The North-West University in Potchefstroom, South Africa, commissioned a dedicated solar telescope observatory in 2021. Since its inception several postgraduate projects have been completed using the solar telescope. This study focuses on the latitudinal dependence of the photospheric differential rotation rate of sunspots and its relationship to sunspot area. The rotation rates and areas are experimentally determined by using a dedicated hydrogen alpha solar telescope by tracking sunspots across the solar disk for several months. The results are compared with the Solar Observing Optical Network observations extracted from their daily Solar Region Summary. Our results confirm the previously reported underestimation of sunspot areas, and we discuss its relationship with the differential rotation rates.

Features of photoionization of Fe XVII, XVIII, Fe XIX impacting solar opacity

Prof Sultana Nahar

The Ohio State University

Abstract

Iron is the dominant heavy element that plays an important role in radiation transport in stellar interiors. Owing to its abundance and large number of bound levels and transitions, iron ions determine the opacity more than any other abundant element. A few iron ions constitute the abundance and opacity of iron at the base of the convection zone (BCZ) at the boundary between the solar convection and radiative zones, and are the focus of the present study. Together, Fe xvii , Fe xviii and Fe xix contribute 85% of iron ion fractions 20%, 39% and 26% respectively, at the BCZ physical conditions of temperature T $\sim 2.11 \times 10^6$K and electron density Ne = 3.1×10^{22}cc. We report heretofore the most extensive R-matrix atomic calculations for these ions for bound-bound and bound-free transitions, the two main processes of radiation absorption. We chose large wavefunction expansions which includes core ion excitation to n=2,3,4 complexes enable accuracy, convergence of photoionization cross sections, and inclusion of high lying resonances. The resulting datasets include 454 bound levels for Fe xvii, 1,174 levels for Fe xviii, and 1,626 for Fe xix up to n ≤ 10 and l=0 - 9. Corresponding datasets of oscillator strengths for photoabsorption are: 20,951 transitions for Fe xvii , 141,869 for Fe xviii , and 289,291 for Fe xix . Photoionization cross sections have obtained for all bound fine structure levels of Fe xvii and Fe xviii , and for 900 bound LS states of Fe xix. Selected results demonstrating prominent characteristic features of photoionization are presented, particularly the strong Seaton PEC (photoexcitation-of-core) resonances formed via high-lying core excitation with Δn = 1 that significantly impact bound-free opacity.

Temperature profiles of coronal streamers and pseudostreamers during the full solar cycle

Marek Stęślicki[1], Urszula Bąk-Stęślicka[2]

[1]Space Research Centre Polish Academy of Sciences. [2]Astronomical Institute, University of Wrocław, Poland

Abstract

Both coronal streamers and pseudostreamers are long lived structures of the solar corona, and are very important source of slow solar wind. We have analyzed 200+ coronal streamers and pseudostreamers observed by AIA/SDO, from 2011 to 2023. For each streamers we applied a Differential Emission Measure method to obtain both a temperature distribution and a value of average temperature as well as it's change with height above photosphere. We find that streamers and pseudostreamers are filled with plasma with temperatures in the range of 1.2-2.0 MK, but height-temperature profiles of both streamer types differ slightly. Additionally the average temperatures of streamers vary with the solar cycle, and the temperature difference of ~0.7 MK is consistent with slow wind temperature variation.

Advances and Future Directions in Modeling Total and Spectral Solar Irradiance

Dr. Serena Criscuoli

National Solar Observatory

Abstract

Variations of the electromagnetic radiation emitted by the Sun affects life on Earth. Similarly, the spectral energy distribution of stars and its variability affect the habitability of exoplanets and their detectability. In this contribution I will give a review of models of Total (TSI) and Spectral Solar (SSI) irradiance, developed to model variability of the solar electromagnetic spectrum at different temporal scales. I will focus on the advancements in radiative transfer models and techniques that are needed to improve our capability to reproduce and predict spectral irradiance variability, especially in the UV and chromospheric lines, and will describe the crucial role that new and future facilities will play in improving solar and stellar irradiance models.

Lessons learned From The Magnetic Flux Rope Modeling

Dr. Teresa Nieves-Chinchilla[1], Dr. Andreas Weiss[2], Dr. Sanchita Pal[2], Ayris Narock[2,3]

[1]Heliophysics Science Division, NASA Goddard Space Flight Center. [2]Heliophysics Science Division, NASA Goddard Space Flight Center, USA. [3]ADNET, USA

Abstract

Magnetic Flux Ropes (MFRs) are very common structures in the Heliosphere and traditionally associated with Coronal Mass Ejections (CMEs). Inferred from the in-situ observations and sometimes remotely observed, the internal structure of CMEs is assumed to be an organized bundle of magnetic field lines, twisting around a common axis, confining plasma, and dragging away a large part of the Sun's or a planet's atmosphere. Thus, MFRs dominate the transport of energy, mass, and helicity from the Sun to the heliosphere and from the heliosphere to the planets' local environment and determine the impact of space weather activity. The three-dimensional characterization of magnetic flux-ropes observed in the heliosphere has been a challenging task for decades. This is mainly due to the limitation to infer the 3D global topology and the physical properties from the 1D time series from any spacecraft, the gap of information to reconcile with the in situ measurements with remote sensing observations and the limitations imposed by currently available measurements and techniques.

To advance our understanding of magnetic flux-ropes, here we will present the efforts to development of more realistic 3D flux-rope physical modeling that allow us to reconnect the local observations with the global structure. This effort is combined with artificial intelligence technique to automatically detect FRs in solar wind data and additionally determine their geoeffective/non-geoeffective characteristics.

Sunspot inclination of leading and tail magnetic field polarity

Mrs. Kseniia Tlatova, Mr. Andrey Tlatov

Kislovodsk Mountain Astronomical Station GAO RAS

Abstract

We investigated the inclination of sunspots a relative to the vertical. To determine the deviation angle a, a method was used to search for differences at different distances of sunspots from the central meridian, in the eastern and western hemispheres of the Sun. Particular attention is paid to the difference in angles a for spots of leading and tail polarity of the magnetic field. It has been established that the angles of deviation of sunspot umbra from the vertical depend on the logarithm of the area, but have opposite signs for leading sunspot umbra's and for umbra's tail polarity. When the magnetic field is Bmx~1500 G, the deviation angle a is approximately equal to zero. The found dependencies indicate the ascent of U-shaped force tubes.

Multi-scale structure of Interplanetary Coronal Mass Ejections

Emilia Kilpua

Univeristy of Helsinki

Abstract

Interplanetary Coronal Mass Ejections (ICMEs) are macroscale structures in the heliosphere that drive intense space weather disturbances at the Earth and other planets of the solar system. A typical ICME consists of a leading fast forward shock wave, turbulent and compressed sheath region and a magnetic obstacle (magnetic cloud or a flux rope, or a more complex ejecta). This presentation will give an overview of the multi-scale structure of ICMEs. Sheaths and magnetic obstacles behind them are macroscale structures with radial widths of a significant fraction of an astronomical unit. Both however feature significant internal structuring, for example sheath regions have frequently mesoscale structures embedded such as small flux ropes and reconnection exhausts. These smaller scale structures have an importance for driving magnetospheric disturbances and accelerating charged particles. Turbulent properties, including level of magnetic field fluctuations, intermittency, cross-helicity, residual energy and magnetic helicity will be also discussed.

Are there local dynamos acting in sunspot regions?

Dr. Chunlan Jin

National Astronomical Observatories, Chinese Academy of Sciences

Abstract

A long lonely question in solar physics is whether or not there are local dynamo or dynamos acting in sunspot regions. Here we present an observed pattern of magnetic evolution implying a type of local dynamo does make the sunspots alive with ample complexity and energy. The unusual pattern is shown by peculiar bipolar magnetic emergences (BMEs) surrounding a mature unipolar sunspot with the following characteristics: (1) BMEs persistently appear beyond the penumbra, encircling the sunspot in end-to-end connection; (2) each BME gradually grows and separates its two polarities along an arc trajectory centered on sunspot; (3) a circular brightening belt is manifested in the ultraviolent/extreme-ultraviolent radiations during the BMEs'evolution; (4) often the sunspot regions with such flux emergence have vigorous solar activity, e.g., homogeneous major flares. Seven active regions (ARs) are definitively identified to host the above typical evolving pattern, which suggests a local twisted-reconnection dynamo operating in these sunspot regions.

Helioseismic Diagnostics of Emerging Active Regions and Their Flaring Activity

Alexander Kosovichev[1], Viacheslav Sadykov[2]

[1]New Jersey Institute of Technology, Newark, NJ 07102, USA. [2]Georgia State University, Atlanta, GA 30303, USA

Abstract

We investigate the evolution of subsurface flows during the emergence and the active phase of sunspot regions using the time-distance helioseismology analysis of the full-disk Dopplergrams from the Helioseismic and Magnetic Imager (HMI) onboard the Solar Dynamics Observatory (SDO). We present an analysis of emerging active regions of various types, including delta-type active regions with high flaring activity and regions with the reverse polarity order (`anti-Hale active regions'). The results reveal strong vortical and shearing flows during the emergence of magnetic flux, as well as large-scale converging flow patterns around developing active regions, predominantly in the top 4 Mm deep layers. The delta-type and anti-Hale active regions, which originated from the interaction of new emerging flux with the previously formed sunspots in our case studies, were associated with complex subsurface flow patterns. Our analysis revealed a significant correlation between the flow divergence and helicity in the active regions with their flaring activity. The strongest Kendall's tau rank correlation coefficients of the flow descriptors (the total divergence, vorticity, and helicity averaged over the 30x30-degree patches) with the flare productivity within the next 24-hour window, were found for subsurface flows at 1-3 Mm depth. This work shows the potential for using subsurface flow measurements to improve flare forecasting.

[1]Harvard-Smithsonian Center for Astrophysics. [2]European Space Agency. [3]NASA Goddard Space Flight Center. [4]NASA Marshall Space Flight Center. [5]University of Hawaii

Abstract

In April 2024, the High Resolution Coronal Imager (Hi-C Flare) and the Focusing Optics X-ray Solar Imager (FOXSI-4) rockets are planned to launch sequentially during the soft X-ray flux raising phase of a large solar flare. This NASA sounding rocket Flare Campaign is designed for a coordinated solar flare observation with the latest EUV and X-ray instrumentation. A ride-along instrument to the Hi-C Flare payload is the Swift Solar Activity X-ray Imager (SSAXI-Rocket. In the short 5-minute rocket flight, SSAXI-Rocket will measure the soft X-ray near-peak emission phase of a GOES C-class or greater solar flare. The SSAXI-Rocket instrument has peak sensitivity to 10 MK solar plasma, similar to the current Hi-C flare instruments, providing the exploration of the variability in heating and energy transport of Solar flares. SSAXI-Rocket combines small X-ray focusing optics with on-axis imaging resolution of 10 arcseconds or better and high speed readout detector, to image the flare soft X-rays at 5 hertz or faster, with minimized image saturation and pixel signal blooming. These high time cadence measurements can help uncover the soft X-ray intensity variations which can provide constraints on the intermittent heating processes in the magnetic loops.

The dust-heliosphere connection

Dr. Veerle Sterken

ETH Zürich

Abstract

Interstellar and interplanetary dust in the solar system acquire a surface charge as they are irradiated by the Sun and move through the heliospheric plasma. In situ spacecraft with dedicated dust instruments or with plasma wave antennas can measure these dust fluxes and in some cases the surface charges of cosmic dust. Several dust-heliosphere interactions are known from previous missions. For instance, interstellar dust focuses and de-focuses with respect to the solar equatorial plane depending on the 22-year Hale-cycle due to Lorentz forces. This was measured by a.o. the Ulysses and Galileo dust instruments and the Wind and STEREO plasma wave antennas. Also, the measurement of Jovian dust streams consisting of nanometers-sized dust particles are known to be correlated with transient structures in the solar wind.

In this talk we review the latest results and the prospects concerning dust-heliosphere interaction processes. In particular, we emphasize the current knowledge concerning the interstellar dust modulation by the heliosphere and the heliosheath. We highlight unique in situ measurement opportunities in the 2030 dust focusing phase - and beyond. Such measurements can happen at 1 AU with "local" spacecraft or, e.g. with a dust instrument on the Lunar Gateway - and across the heliosphere with an Interstellar Probe. We report on the discovery of a solar rotation frequency in the dust data, measured by plasma wave antennas, and elaborate on its possible causes. Finally, we argue that future missions with joint plasma and dust instrumentation are needed to foster synergies between dust and heliospheric sciences.

The non-thermal emission from the quiet Sun

Elena Orlando

University of Trieste and INFN

Abstract

The observed electromagnetic spectrum of the Sun in its non-flaring state extends from radio up to hundreds of GeV. In fact, the Sun is a recently-known gamma-ray source also in its quiet state. This high-energy emission is supposed to originate from interactions of Galactic cosmic rays with the solar surface and its surroundings.
We provide an overview of our current theoretical expectations and of present observations of the steady emission from the Sun from gamma rays to radio produced by galactic cosmic rays. We discuss how observations impact our knowledge of the solar environment and on galactic cosmic rays.

[1]Inter-University Centre for Astronomy and Astrophysics (IUCAA), Pune, India. [2]Tezpur University. [3]Manipal Centre for Natural Sciences, Manipal Academy of Higher Education, Manipal -576104. [4]U.R. Rao Satellite Center, Bengaluru, India

Abstract

The Solar Ultraviolet Imaging Telescope (SUIT) onboard India's Aditya-L1 mission takes spatially resolved full-disk images of the Sun in the 200-400 nm wavelength band. With eleven bandpasses, SUIT can explore various altitudes of the solar atmosphere and study the mass and energy transfer mechanisms.

SUIT aims to observe dynamic solar features like flares and jets and magnetic phenomena like plages, active regions, and network regions, spanning diverse scales in the solar atmosphere. Solar emission in this wavelength range is also highly significant for understanding the Ozone-Oxygen chemistry and the Sun-Earth climatic connection, making SUIT a unique addition to the existing instruments.

The scientific goals of SUIT require reliable photometric calibration to derive the associated absolute radiative energies. The instrument throughput is modeled using sun-as-a-star solar spectra from SOLSTICE and SOLSPEC for all science filters. This is validated by measuring the radiometric response of the instrument in the lab. The payload is loaded in a contamination-controlled vacuum chamber, and monochromatic light of known energy and wavelength is collimated and fed into the chamber. The measured counts are compared with the modeled values, revealing >85% coherence.

This presentation demonstrates the experimental setup, precautions, complete methodology, and related test results. The ratio of modeled data numbers to measured values is close to 1, while the spectral response of the payload isseen to closely match the model. The technology and methods employed are anticipated to be significant to the calibration of ground and space-based instruments in the future.

Electron-Scale Electric Field Turbulence in the Solar Wind: Clues to understanding energy dissipation

Dr Chadi Salem[1], Dr John Bonnell[1], Dr Kristopher Klein[2], Dr Luca Franci[3], Dr Vadim Roytershteyn[4]

[1]University of California Berkeley, USA. [2]University of Arizona Tucson, USA. [3]Northumbria University, Newcastle, UK. [4]Space Science Institute, Colorado, USA

Abstract

Recent works on solar wind turbulence and dissipation suggest that kinetic-scale fluctuations are both heating and isotropizing the solar wind during transit to 1 AU. The nature of these fluctuations and associated heating processes are poorly understood. The Electric Field is key to understanding the nature of the dissipative processes (Landau damping, cyclotron damping, stochastic heating, or energization through coherent structures) that link fields and particles.

The dissipation due to the fluctuations depends intimately upon the temporal/spatial variations of those fluctuations in the plasma frame. In order to derive that distribution in the plasma frame, one must also use magnetic field and density fluctuations, in addition to electric field fluctuations, as measured in the spacecraft frame (s/c) to help constrain the type of fluctuation and dissipation mechanisms that are at play.

We present an analysis of electromagnetic fluctuations in the solar wind from MHD scales down to electron scales using data from the Artemis spacecraft at 1 AU. We analyze magnetic and electric field, and density fluctuations from the 0.01 Hz up to 1 kHz. We compute electric to magnetic field ratio, magnetic compressibility, magnetic helicity, compressibility and other relevant quantities in order to diagnose the nature of the fluctuations at those scales, extracting information on the dominant modes composing the fluctuations, and compare to expectations from linear theory. These results are supplemented by analysis of fully nonlinear kinetic simulations of decaying turbulence at small scales.

Evolution of Ratio of Mg II Intensities During Solar Flares

Soumya Roy, Durgesh Tripathi

The Inter-University Center for Astronomy and Astrophysics

Abstract

The ratios of Mg II k & h line intensities offer a valuable means to explore plasma properties within the solar atmosphere. In this investigation, we analyse observations obtained by the Interface Region Imaging Spectrometer (IRIS) to examine how the Mg II k & h intensity ratio varies across the evolution of three different flares: X-class, M-class, and C-class. Additionally, we investigate the relationship between the k-to-h intensity ratio and the magnetic flux density derived from line-of-sight magnetograms captured by the Helioseismic and Magnetic Imager (HMI) aboard the Solar Dynamics Observatory (SDO). Our findings demonstrate that although the intensity ratios remain unaffected by magnetic flux density, they undergo significant changes during the progression of C-class and M-class flares. Specifically, these ratios begin to rise at the onset of the flare, reaching a peak during the impulsive phase before the flare reaches its maximum, followed by a rapid decline after that. During the peak and decline phases of the flare, the ratios plummet even below their pre-flare levels. These observations shed light on plasma's localised heating and cooling, thus adding valuable insights to our understanding of flare physics.

Estimating magnetospheric current systems during geomagnetic storms: Comparison of Inner-Magnetosphere and Ionosphere modeling with ground and space-based magnetic field observations

Dr Ephrem Tesfaye Desta[1,2], Dr Mei-ching Fok[3], Prof Mark B. Moldwin[4], Prof Tigistu Haile Eritro[5]

[1]Center for Space Research, North-West University (Potchefstroom Campus). [2]Department of Physics, Addis Ababa University, King George VI St., Addis Ababa, 1176, Ethiopia. [3]NASA Goddard Space Flight Center, Greenbelt, Maryland, 673, USA. [4]University of Michigan, Climate and Space Sciences and Engineering, 2455 Hayward St., Ann Arbor Michigan, MI4810, USA. [5]School of Earth Science, Addis Ababa University, King George VI St., Addis Ababa, 1176, Ethiopia

Abstract

During geomagnetic storms, solar wind energy is coupled into the magnetosphere, creating and amplifying the global magnetospheric current system. Rapid plasma transport, ULF wave propagation, and enhanced pressure gradients through the magnetosphere intensifies high-latitude field aligned currents (FACs) and equatorial current systems, respectively. We report the effect of solar wind dynamic pressure and particle density enhancements on the FAC, Ring Current (RC), RC energy injection and associated magnetic fluctuations by multipoint magnetic observations from ground and space in the equatorial plane. In this study,(1) the solar wind dynamic pressure, particle density, and IMF B_z during geomagnetic storms are examined; (2) magnetic data from four geomagnetic equatorial stations measuring ground magnetic disturbances across a wide range of geomagnetic equatorial longitudes for the storm periods 17 March 2013, 31 May-01 June 2013, and 05-08 July 2013 are analyzed; (3) using ground magnetometer data, the magnetic field disturbance (dH) across the equator and the Dst index, ring current and ring current energy content are estimated at r = 4.5 R_e; and (4) for corresponding geomagnetic storm periods using the Van Allen Probes and THEMIS spacecraft data, the FACs were estimated. (5) Inner magnetosphere (CIMI) and lower ionosphere model (SAMI2) also used for the event analysis. Our results show that the sudden enhancement of solar wind pressure, proton density and strong southward reversal orientation of IMF B_z lead to strong geomagnetic storm that increases ring current asymmetry over geomagnetic equator and rapid peak variations in FAC. The results also show that when geomagnetic storms persist longer, variations in equatorward Field-Aligned Currents (FAC) last longer as well

Investigating the response of the topside ionosphere to space weather and solar activity using Global Navigation Satellite System positioning

Dr Joseph Omojola

North-West University

Abstract

This study investigates the response of the ionosphere to space weather events and solar activity by single-point post-processing analysis of the Global Navigation Satellite Systems (GNSS) archival data from the International GNSS Service (IGS) over Addis Ababa with station ID ADIS and Sutherland with Station ID SUTV in the African sector. The data were selected during the solar minimum and maximum of solar cycle 24, during the geomagnetic storm that occurred on 16-18 March 2015 and the quiet days on 6-8 January 2010. The storm began with a sudden commencement at 5:00 UT on 17 March 2015, reaching the main phase on the same day with a minimum SYM-H index of -234 nT at 22:47 UT. The X-Ray Telescope (XRT) onboard Hinode also show an X-ray irradiance with several active regions and coronal holes on the solar disk during this period. The observation of the solar disk by Hinode on the 7th and 8th of January 2010 is interesting, during which the development of the active region and the coronal holes can be easily observed, and its signature was detected prominently at SUTV, a mid-latitude station. The results indicate that GNSS positioning is very sensitive to solar activity and can be useful in studying solar-terrestrial interactions.

Signature of self-absorption in the Si IV emission lines from a solar surge

Mr B. Suresh Babu, Dr Pradeep Kayshap, Dr Sharad Chandra Tripathi

VIT Bhopal University

Abstract

Interface Region Imaging Spectrograph (IRIS) has observed a surge that occurred at the periphery of an active region (AR) on October 17, 2023. The multi-wavelength images from Atmospheric Imaging Assembly (AIA) revealed that the jet is visible only in the cool temperature filters, with no hot jet signature. The projected propagation speed of the jet, deduced from the time-distance analysis, is around 200 km/s in the cool temperature filters. The spectroscopic diagnostic shows that the base of the surge is highly red-shifted while the spire of the jet is blue-shifted. Most importantly, some Si IV spectral profiles from the base and spire of the surge have a dip at the central wavelength, which is the signature of self-absorption. Here, we emphasize that this is the first observational evidence of self-absorption in the jet-like structure. Then, we estimated the Si iv line ratio (1393.755 Å/1402.70 Å) and found that most of the locations in the base and the spire of the surge have ratio values less than the theoretical value of 2.0. This supports that the Si IV spectral lines are forming under optically thick conditions. Further, the electron density is estimated using the O IV spectral lines (1393.78 Å and 1401.16 Å) and the CHIANTI atomic database. The mean electron density at the base is log 10.82 and at the spire of the surge is log 9.93. The observational evidence (e.g., anemone shape, and brightening at the base) supports that this particular surge is triggered by magnetic reconnection.

Observational Validation of the Modeling and Simulation of a CME using a Deep Neural Network

Dr Diego Lloveras[1], Dr. Hebe Cremades[1], Dr. Francisco Iglesias[1], Florencia Cisterna[1], Dr. Alberto Vasquez[2], Dr Federico Nuevo[2], Dr Ward Manchester IV[3], Dr Nishtha Sachdeva[3]

[1]Grupo de Estudios en Heliofísica de Mendoza, CONICET, Universidad de Mendoza, Mendoza, Argentina. [2]Insituto de Astronomía y Física del Espacio, CONICET--UBA, Argentina. [3]Climate and Space Sciences and Engineering, University of Michigan, USA

Abstract

Coronal mass ejections (CMEs), huge structures of plasma and magnetic field that are expelled from the solar corona into the solar wind, play a determining role in the evolution of space weather and climate. A detailed understanding of the physical mechanisms that govern CME dynamics requires the combination of observations with theoretical modeling and numerical simulation. In this work, we use the three-dimensional (3D) magnetohydrodynamic Alfvén Wave Solar Model to simulate the background corona and solar wind. To simulate the CMEs, we use the Eruptive Event Generator Gibson-Low module (EEGGL), which provides an initial flux-rope type magnetic configuration that is allowed to evolve into the interplanetary medium. We use a Deep Neural Network to identify and segment the outer envelope of CMEs in a time series of single images provided by
SOHO/LASCO-C2, and STEREO/COR2, which allows us to calculate CME parameters (such as angular width and central position angle) using the segmentation masks. We used the parameters obtained from the real image segmentation to validate the simulated synthetic images from the CME. In this presentation, we show the analysis applied to a selected event, whose observations are used to validate the simulation's ability to successfully model this CME.

The Sun's differential rotation is controlled by baroclinically-unstable high-latitude inertial modes

Dr. Yuto Bekki[1], Dr. Robert Cameron[1], Prof. Dr. Laurent Gizon[1,2]

[1]Max Planck Institute for Solar System Research. [2]University of Göttingen, Institute for Astrophysics

Abstract

Global p-mode helioseismology has revealed that the Sun’s differential rotation substantially deviates from the well-known Taylor-Proudman theorem. It has been postulated that this deviation is due to the poles being warmer than the equator by a few degrees. However, this latitudinal temperature difference is too small to be directly measured. Recently, various inertial modes have been observed and identified on the Sun, including modes at high latitudes. These high-latitude inertial modes are baroclinically unstable and thus quite sensitive to the latitudinal temperature difference in the Sun. In this talk, using 3D nonlinear numerical simulations, we show that the pole-to-equator temperature difference in the Sun is limited to less than 7 K due to the nonlinear feedback of the high-latitude modes. It is also found that these inertial modes control the Sun's differential rotation by transporting heat equatorward and driving the meridional circulation to redistribute the angular momentum. The observed amplitudes of these inertial modes indicate that the Sun's latitudinal differential rotation is near its maximum allowed value.

First detailed polarimetric study of a type-II solar radio burst with the Murchison Widefield Array

Ms Puja Majee[1], Mr Devojyoti Kansabanik[2,3], Mr Divya Oberoi[1]

[1]National Centre for Radio Astrophysics, Pune, India. [2]University Corporation for Atmospheric Research, Boulder, CO, USA. [3]Hosted at Johns Hopkins University, Applied Physics Laboratory, Laurel, MD, USA

Abstract

Type II solar radio bursts are plasma emissions generated by magnetohydrodynamic shocks that are predominantly associated with the more energetic and fast coronal mass ejections (CMEs). These CMEs are expected to drive shocks in the coronal medium and play a dominant role in giving rise to energetic particles which are the biggest concern for Space Weather. The evolution and geo-effectiveness of these eruptions are governed by their magnetic fields and interaction with the coronal magnetized plasma; hence, crucial to understand. Polarimetric properties of type-IIs provide promising diagnostics for measuring and understanding the magnetic field strength, and topology at the CME-shocks. In the literature, their polarization properties have been reported to vary from being unpolarized to very strongly circularly polarized, and no linear polarization has ever been reported. The vast majority of these studies rely on dynamic spectra which can only provide spatially integrated information. Instruments like the Murchison Widefield Array (MWA) and robust spectropolarimetric snapshot solar imaging pipeline, P-AIRCARS, (Kansabanik et al., 2022a, 2022b, 2023) have enabled high-fidelity and high-dynamic range solar radio imaging with good temporal, spectral and reasonable angular resolution. Benefiting from these, we have used this capability to carry out a detailed imaging polarimetric study of a type-II solar radio burst. We have also characterized the structures of the sources in both the total intensity and polarized emissions, meticulously investigating their temporal and spectral evolutions. Our study marks the start of the use of polarimetric imaging observations to further the understanding of type-II radio bursts and coronal propagation.

ICME deformation rate in their propagation to 1 AU

Lic Franco Manini[1], Dr Hebe Cremades[1], Dr Teresa Nieves-Chinchilla[2], Dr Diego Lloveras[1], Dr Francisco Iglesias[1], Dr Fernando Lopez[1]

[1]Universidad de Mendoza - CONICET - Argentina. [2]NASA Goddard Space Flight Center

Abstract

The 3D shape and internal structure of heliospheric flux ropes is still mostly unknown. Therefore, there is a need to
investigate the interplanetary evolution of Coronal Mass Ejections in the inner heliosphere, mainly due to their impact on Earth and spacecrafts orbiting the Sun and other planets.
In this work we built a list of Earth-directed ICMEs during the years 2010 to 2012. We used the Heliospheric Imagers (HI) aboard the STEREO spacecrafts to identify 366 ICMEs in the FOV of the HI-1 telescopes.
For 28 events, we were able to follow the CMEs from their source region in the Sun and in coronographic images from COR2 and C2 instruments, with their respective interplanetary counterparts using the Heliospheric Imagers HI-1 and HI-2, up to the in situ
plasma measurements made with the WIND and ACE spacecrafts, in the vicinity of Earth. We selected 3 events with their flux rope seen horizontally in HI-1 instruments, to apply different distortion functions using the General Distorted-toroidal flux-rope model, and measure the deformation rate
of the cross section in the different stages of propagation in the FOV. This work is an intent to characterize the changes in the ICMEs complexity as they propagate from the Sun to 1 AU.

Solar coronal structure in the Maunder Minimum and the Dalton Minimum: Archival investigations

Dr Hisashi Hayakawa

Nagoya University. Rutherford Appleton Laboratory

Abstract

This presentation contrasts the coronal structures in the Maunder Minimum (1645 -- 1715) with those in the modern regular solar cycles, the Dalton Minimum, and the immediate aftermath of the Maunder Minimum. The Maunder Minimum was typically considered as the only grand minimum within the coverage of the direct instrumental solar observations in the last 4 centuries. The solar magnetic activity was far calmer than that of the regular solar cycles in the space age -- and probably so than that of the Dalton Minimum (1790s -- 1820s), whereas it is not immediately clear how quiet the solar magnetic activity was. This is because we have limited access to the contemporaneous sunspot observations. In contrast, total solar eclipses in history have occasionally left graphical records. They are especially helpful to understand the solar coronal structure and indirectly visualize the large-scale solar magnetic activity back in the past. This presentation reviews such graphical records for historical total solar eclipses, contesting the solar coronal structures in the Maunder Minimum with those of the modern solar cycles, the Dalton Minimum, and the immediate aftermath of the Maunder Minimum, including developments from Hayakawa et al. (2021, JSWSC, 11, 1). These results strikingly contrast the Maunder Minimum with the modern solar cycles, the Dalton Minimum, and the immediate aftermath of the Maunder Minimum, to emphasize how unique the Maunder Minimum was.

Solar X-ray Irradiance Observations from the Miniature X-ray Solar Spectrometer (MinXSS) CubeSats

Crisel Suarez[1,2], Christopher S. Moore[2], Amir Caspi[3], Phil Chamberlin[4], Brendan D'Aquino[2], Anant Kumar[5], James Mason[6], Bennet Schwab[4], Robert Sewell[4], Tom Woods[4]

[1]Vanderbilt University. [2]Center for Astrophysics | Harvard & Smithsonian. [3]Southwest Research Institute. [4]Laboratory for Atmospheric and Space Physics. [5]University of Alberta. [6]Johns Hopkins University Applied Physics Laboratory

Abstract

The Miniature X-ray Solar Spectrometer (MinXSS) CubeSats were the first solar science-oriented CubeSat mission flown for the NASA Science Mission Directorate, with the main objective of measuring the absolute radiometrically calibrated energy distribution of solar soft X-ray emission over a large spectral bandpass at a moderate spectral resolution (nominal 0.15 keV energy resolution at 5.9 keV). The MinXSS Cuebsats were successful in measuring the solar soft X-ray irradiance in the energy range of 0.8 - 12 keV. The first of the twin CubeSats, MinXSS-1, has observed over 30 solar flares from June 2016 to May 2017 over its 1-year mission lifetime. MinXSS-2 observed the quiescent Sun during December 2018-January 2019. Since February 2022, the next generation MinXSS, the Dual Aperture X-ray Solar Spectrometer (DAXSS), has been conducting higher sensitivity and higher spectral resolution measurements. The spectral measurements and unique energy resolution at the time, provided by MinXSS can constrain solar flare and active region temperature structure, emission measure, and abundances of Fe, Ca, Si, and, S. We present the science results of the MinXSS-1 and MinXSS-2 measurements for flares and the quiescent Sun. These results have proven to be consistent with numerous solar observations from other satellites, and provide constraints in modeling and understanding solar phenomena, therefore proving the scientific capabilities of CubeSats.

Opening New Frontiers in Solar Radio Physics Using High-fidelity Imaging Observations with Square Kilometre Array Precursors

Dr DEVOJYOTI KANSABANIK

Cooperative Programs for the Advancement of Earth System Science (CPAESS), Corporation for Atmospheric Research, Boulder, CO, USA. Applied Physics Laboratory, Johns Hopkins university, LAUREL, MD, USA. National Centre for Radio Astrophysics, Tata Institute of Fundamental Research, Pune, India

Abstract

Solar radio emissions and their polarization properties provide the means to remotely measure plasma parameters including magnetic fields of the solar atmosphere as well as different eruptive phenomena like flares and coronal mass ejections (CMEs). However, observing radio emissions from all of them is intrinsically challenging. These emissions show morphological structures ranging from a few arcseconds to a few solar radii. Additionally, their brightness spans more than ten orders of magnitude and shows dramatic variation in both spectral and temporal dimensions. Hence, one requires high dynamic-range (DR) spectropolarimetric snapshot imaging to observe them in detail. We have developed the state-of-the-art polarimetric calibration and imaging pipeline (P-AIRCARS; Kansabanik et al., 2022, 2023) over the last few years. P-AIRCARS now routinely provides high DR spectropolarimetric meter-wavelength solar images using observations from the Murchison Widefield Array (MWA), the precursor of the low-frequency telescope of Square Kilometer Array Observatory (SKAO). These high DR images have led to several new results – quiet Sun magnetic field estimation using measurements of low levels circular polarization, spectropolarimetric modeling of faint gyrosynchrotron (GS) emission from CMEs providing robust estimations of its plasma parameters. Alongside, we have recently started solar observations at GHz frequencies with MeerKAT, the mid-frequency precursor of the SKAO. Comparing the very first MeerKAT solar images with simulation, we demonstrated its capability to produce high-fidelity solar images at GHz frequencies. This talk will give glimpses of new results from both of these instruments establishing the ability of SKAO to open up new frontiers in solar radio physics.

[1]High Altitude Observatory, National Center for Atmospheric Research. [2]University of Graz. [3]Kanzelhöhe Observatory for Solar and Environmental Research

Abstract

Artificial intelligence (AI) has enabled ground-breaking results across scientific domains. With the rapid increase in data volume and computational complexity, astrophysics can directly profit from the most recent breakthrough methods of artificial intelligence. In this presentation we give an overview of the six research papers that comprise the thesis and that address recent frontiers of artificial intelligence in solar physics. Leveraging cutting-edge AI techniques, these studies are key to extract unprecedented information from large data sets, spanning the applications from precise detection of coronal hole boundaries to transformative imaging translation and real-time magnetic field extrapolations. By bridging historical observations, enhancing data accessibility, and unlocking new dimensions of the structure of the solar corona, these advancements mark a significant step forward in our ability to comprehend the complexities of the Sun and its dynamic behavior.

In this talk, we specifically focus on the transformative role of physics-informed neural networks (PINNs) for modeling of the solar corona, where we use photospheric and chromospheric magnetic field measurements to estimate the magnetic topology in the upper solar atmosphere.

With this we underscore the remarkable addition and synergy that artificial intelligence brings to solar physics.

How to deflect a solar eruption

Abril Sahade[1], Mariana Cécere[2,3]

[1]NASA Goddard Space Flight Center, Maryland, USA. [2]Instituto de Astronomía Teórica y Experimental, Córdoba, Argentina. [3]Observatorio Astronómico de Córdoba, Córdoba, Argentina

Abstract

Understanding the properties, evolution, and geoeffectiveness of coronal mass ejections (CMEs) is of utmost importance for space weather forecasting. CMEs originate from an erupting magnetic flux rope (MFR), and are usually related with erupting filaments and flares. Not all CMEs evolve radially, and deviations in the trajectory are mainly attributed to interactions with magnetic structures surrounding the eruption source region, coupling between successive events, and asymmetric detachment of the MFR. However, the extent to which each process influences the MFR deflection is still under investigation. The research conducted in this work focuses on understanding how the interaction between the erupting MFR and the magnetic environment of the source region leads to a deflection. In particular we investigated the role of coronal holes and pseudostreamers using magnetohydrodynamic (MHD) 2.5 simulations and compared them with observational cases. We conclude that null points play a key role in deviating erupting flux ropes. By identifying the null point location, hierarchy and the environment topology we may improve our understanding of the early development and trajectory of solar eruptions.

An Earth-sized Exoplanet Orbiting an M2 Star

Mr Francis Zong Lang, Professor Brice-Olivier Demory

University of Bern

Abstract

The population of rocky exoplanets are abundant and cool
stars such as M-dwarfs provide a unique opportunity to detect these objects
with possible implications for the study of Astrobiology.

SAINT-EX (Searching And characterisINg Transiting EXoplanets) consists of a
one-meter telescope optimized to obtain high-precision light curves of transiting
planets orbiting ultra-cool stars. The two main objectives of SAINT-EX are:
-The search of terrestrial exoplanets orbiting ultra-cool stars and
-To give ground-based support to the ESA CHEOPS mission.

TOI4616, a system with a planet of size 1.22R$\oplus$ and an orbital period of 1.554
days has been detected by the NASA TESS mission and later characterized
with the SAINT-EX telescope. We study this system in order to characterise
the properties of the planet and its host star and use transit photometry to con-
strain critical parameters of the planet such as its mass and orbital dynamics.
By employing a series of aperture and PSF photometry methods to determine
the crowding metric and the flux fraction to compute an accurate transit depth
obtained from the SAINT-EX light curves and constrain the necessary plane-
tary parameters.

The validation of the orbital period of 1.554 days reinforces our understand-
ing of rocky exoplanets around low-mass stars. We expect TOI4616 to be a
rocky exoplanet with the possibility of hosting an atmosphere. Analysis through
transmission spectroscopy might offer insights into the exoplanet's atmosphere,
revealing potential molecular constituents. Investigating the planet's stability
in this system would reveal potential interactions with other bodies and the system's long-term stability.

The Dynamical Evolution of Planets Orbiting Interacting Binaries

Dr Santiago Torres

Institute of Science and Technology Austria (ISTA)

Abstract

15% of solar-type stars are in such close binaries that interaction is bound to occur as the stars evolve and swell. Around 20 circumbinary planets have been detected orbiting binary systems. This suggests that dynamical processes play a key role in the evolution of circumbinary planetary systems. Understing the interaction between the bodies in such complex systems is important for planet formation and binary evolution. The tightest orbit binaries should host the most stable and, therefore, long-lived circumbinary planetary systems. Still, they are also the systems that are expected to experience mass transfer, common envelope evolution, or stellar mergers. Subdwarfs are one of the most common types of products resulting from binary evolution. They are both long-lived and easy to recognize. In order to disentangle the dynamic evolution of planets around evolved and interacting binaries, we developed an integration framework that seamlessly integrates the binary evolution data from the stellar evolution code MESA into a detailed N-body simulation code REBOUND. To ensure numerical robustness, we constructed a binary star model and introduced a recalibration method to mitigate errors from updates of binary properties during dynamical computations. We reveal that the nearest stable orbital separation for circumbinary planets is roughly 2.5 times the binary separation after mass transfer. In this talk, I will present our new method, model and latest results of the evolution of planets whose host binary evolves into a subdwarf system.

The demographics of small transiting exoplanets

Dr Rafael Luque

The University of Chicago

Abstract

The diversity of the exoplanet population is beyond our imagination. The more than 5000 known exoplanets vastly differ in mass, size, orbital period, dynamics, and host type. Demographic studies, however, aim to find patterns in the population that inform us about their origin, composition, and evolution. Among these features, perhaps the most surprising is the abundance of planets with no analog in the solar system, also known as sub-Neptunes. In this talk, I will review the state-of-the-art regarding the detection and characterization of such planets and what we know today about their enigmatic nature. A definitive answer, however, seems within reach during this decade thanks to the game-changing observations that will be provided by JWST, PLATO, and ARIEL.

A new ARM-based CPU implementation of the RHPIC-LBM code

Professor Bojing Zhu

Yunnan observatories of Chinese Academy of Sciences. Center of Astronomical Mega-Science, Chinese Academy of Sciences. State Key Laboratory of Space Weather, National Space Science Center, Chinese Academy of Sciences. Earth and Planetary College & School of Astronomy and Space Science, University of Chinese Academy of Sciences

Abstract

We present a new version of the RHPIC-LBM code, applied to investigating the GeV-level-SEPs-induced extreme space weather disasters with a plasma statistical physics theoretical model.

This new implementation, which we have named RHPIC-LBM-Phyton, uses ARM architecture to allow the code execution on the Embedded Central Processing Unit (Phyton E3000 CPU). The Phyton version is an unofficial, modified SUGON version of the RHPIC-LBM code previously designed for the X86 architecture heterogeneous system (CPU-DCU).

We perform numerical simulations based on the previous SUGON version and its Phyton CPU counterpart to conduct performance analysis, including execution time, precision differences, and accuracy. We narrowed our tests and analysis only to double-precision floating point operations and a spherical domain with a 12000 Km fine-structure test (turbulence magnetic fields change around the below and above the loop in the top of the 3D circular flaring coronal loop arcade).

Our comparison shows that results are similar for both versions of the code, confirming the correctness of our ARM-based implementation. Our tests reveal that the RHPIC-LBM Phyton version code can be four times faster than the SUGON version.

Radioactivity of Saturn's D-Ring

Dr James Welsh[1,2], Dr Andrew Karam[3]

[1]Loyola University Stritch School of Medicine. [2]Edward Hines Jr VA Hospital. [3]National Urban Security Technology Laboratory

Abstract

Saturn's rings are the most recognizable feature in our Solar System. Given the extent of Saturn's magnetosphere and radiation belts, it is natural to wonder if the radiation might induce radioactivity in the ring fragments. We have systematically examined activation of the D-ring by considering the following:

1. Radiation flux and energy spectrum
2. Radiation species
3. Elemental composition of the rings
4. Potential nuclear activation channels
5. Interaction cross sections
6. Activation product half-lives

Saturn's rings are 99.9% water ice with traces of organic and silicate impurities. Hence, ^{1}H and ^{16}O are the principal nuclides available for induced activation. Other nuclides include ^{2}H, ^{17}O, and ^{18}O. Minute quantities of tholins and silicates introduce targets of ^{12}C, ^{13}C, ^{14}N, ^{15}N, and ^{28}Si, ^{29}Si, and ^{30}Si. CRAND protons are the most likely source of radiation in the inner radiation belt. We reviewed multiple potential proton capture channels involving the available nuclides; possibilities include:

- High interaction probability, but the products are not radioactive.
- Low activation probability.
- Low abundance of parent isotopes for producing radioactive products
- High activation probability, but only for low energy radiation.
- High activation probability at the energies available.

We conclude that the most likely activation products in the D-ring are ^{11}C, ^{15}C, ^{13}N, ^{14}O, ^{15}O, ^{17}F, ^{18}F, with traces of ^{7}Be, ^{28}Al, ^{14}C, and ^{16}N. As many of these radionuclides are positron emitters, their presence should be readily detectable via characteristic 511 keV annihilation gamma photons.

We note that the ring systems of other planets are amenable to similar analysis.

[5]University of Chinese Academy of Sciences, Beijing, China

Abstract

The *d*-Cancrid meteoroid stream produces 4 meteor showers active on the Earth annually during January-February and August-September. A certain parent comet of the stream is not found. We performed a search for near-Earth asteroids (NEAs) associated with this stream. On the base of calculation of orbital evolution of a sample of NEAs and determination of theoretical features of related showers a search for observable active showers close to theoretically predicted ones was carried out in published databases. As a result, the predicted showers of 13 NEAs were identified with active showers producing by the *d*-Cancrid meteoroid stream. Revealed association points to a common cometary origin of NEAs that are moving within the stream and very likely are extinct fragments of a larger comet-progenitor of the Cancrid asteroid-meteoroid complex.

The depletion of the asteroid belt and the impact history of the terrestrial planets

Julio A. Fernández

Departamento de Astronomía, Facultad de Ciencias, Universidad de la República, Montevideo, Uruguay

Abstract

The asteroid belt has been by far the main source of projectiles that collide with the Earth and the other terrestrial planets. We have analyzed the different escape routes of material from the asteroid belt. Asteroid fragments that do not escape from the belt are ground down by mutual collisions to dust. We find that the asteroid belt is currently losing a fraction of about 7×10^{-5} Myr^{-1} of its mass, about 25% as macroscopic bodies, and 75% as dust particles that feed the zodiacal dust cloud. The computed relative contributions depend on what fraction of zodiacal dust is of asteroidal origin. Estimates can vary between less than 0.1 to about 0.3. Extrapolation of the current mass loss rate to the past suggests only a modest increase of the asteroid belt mass and the mass loss rate (about a factor of 1.3 and 2 respectively) in the last 3.5 Gyr. This should correlate with a modest variation of the impact rate of the terrestrial planets. Yet, should the computed current asteroid mass loss rate be greater than our canonical value, owing to different uncertainties, the extrapolation to the past would lead to quite different results. For instance, an increase by a factor of three in the current asteroid mass loss rate would lead to an exponential increase of the asteroid mass about 3.5 Gyr ago, which would be consistent with models predicting the existence of a primordial massive asteroid belt that decayed on a time scale of 1 Gyr.

Dust growth and pebble formation in the initial stages of protoplanetary disk evolution

Dr. Vardan Elbakyan[1], Dr. Eduard Vorobyov[2], Dr. Prof. Anders Johansen[3], Dr. Michiel Lambrechts[3], Aleksandr Skliarevskii[4], Dr. Vitaly Akimkin[5], Dr. Igor Kulikov[6], James McKevitt[2], Dr. Prof. Manuel Güdel[2]

[1]Universität Duisburg-Essen. [2]University of Vienna. [3]University of Copenhagen. [4]Southern Federal University. [5]INASAN. [6]ICMMG SB RAS

Abstract

We study the dust growth and pebble formation in a protoplanetary disk that is still accreting from a parental cloud core using 3D numerical hydrodynamics code with nested meshes. We found that the dust growth from ∼1 μm to 1–10 mm already occurs in the initial few thousand years of disk evolution. The ratio of the dust-to-gas vertical scale heights remains rather modest, 0.2–0.5. The dust-to-gas mass ratio in the disk midplane is highly non-homogeneous throughout the disk extent and is in general enhanced by a factor of several compared to the fiducial 1:100 value. Low St hinders strong dust accumulation in the spiral arms compared to the rest of the disk, and the non-steady nature of the spirals is also an obstacle. The spatial distribution of pebbles in the disk midplane exhibits a highly non-homogeneous and patchy character. The total mass of pebbles in the disk increases with time and reaches a few tens of Earth masses after a few tens of thousands of years of disk evolution. Hence, young disks with an age ≤20 kyr can already be ripe for the planet formation process to start.

Lightcurves and colors of 11 small Near-Earth Asteroids

Dr. Jean-Baptiste KIKWAYA ELUO[1], Carl W. Hergenrother[2]

[1]Vatican Observatory, V-00129 Vatican City of State, Vatican. [2]Ascending Node Technologies, LLC, Tucson, Arizona, USA

Abstract

We conducted observations of several small near-Earth asteroids (NEA) starting in 2023 using the Vatican Advanced Technology Telescope (VATT) 1.8-m telescope on Mount Graham in southern Arizona. Observations were made for each asteroid in multiple broadband color filters. A long series of V-band images were collected to ensure that the entire lightcurve was covered. In order to compute the color of the asteroid, we also collected images in B, R, and I filters. Petr Pravec's Asteroid Lightcurve (ALC) software was used to compute the lightcurve and determine color indices (V-R, B-V, and V-I) for each asteroid. We use the following methods to determine the asteroid's taxonomy and meteorite classification. The first method consisted of making two-color plots (B-V vs . V-R and V-I vs. V-R) to compare the colors against those of other asteroids. For the second method, we computed the relative reflectance of the NEA, which we compared with the observed asteroid spectra in the SMASS/SMASSII database (Bus and Binzel 2002a,b). The final method consists of a comparison between the relative reflectance of the NEA and the laboratory spectra of meteorites from the Brown University Reflectance Experiment Laboratory (RELAB).

2020 BV14, a H=23.4 Apollo asteroid, is a fast rotator with a rotation of 0.17460+/-0.00006 h. The color indices of B-V=0.781+/-0.029, V-R=0.441+/-0.031, and V-I=0.826+/-0.026 suggest 2020 BV14 belongs to the X-complex of asteroids.

The results for the 11 observed NEAs are shown in Tables 1 (Kikwaya Eluo & Hergenrother, 2023) and 2 ((Kikwaya Eluo & Hergenrother, 2024).

The Vatican Observation Meteor Research Program (VOMRP)

Dr. Jean-Baptiste Kikwaya Eluo[1], Carl W. Hergenrother[2]

[1]Vatican Observatory, V-00129 Vatican City of State, Vatican. [2]Ascending Node Technologies, LLC, Tucson, Arizona, USA

Abstract

The Vatican Observatory Meteor Research Program is collaborating with three meteor and fireball video detection networks. The first collaboration is with cameras operated in Italy as part of Fripon (Fireball Recovery and InterPlanetary Observation Network). The Vatican Observatory's contribution consists of a camera installed in 2022 at Castel Gandolfo. Fripon gathers data on meteors brighter than -4 magnitude with a clear objective of meteorite recovery. The Castel Gandolfo camera has observed more than 20 fireballs since 2022 though none produced meteorites. The goal is to observe fireballs capable of producing meteorites that would then be studied at the Vatican Observatory's meteorite laboratory to determine physical characteristics (density, porosity, heat conductivity, etc.).

The second system operates near Tucson, Arizona, USA, in collaboration with the NASA Asgard All Sky Fireball Network, observing meteors brighter than 3rd magnitude. The Vatican Observatory collaboration includes 3 cameras installed around Tucson on Mount Lemmon, Mount Hopkins and Kitt Peak. Each night, meteors are detected, analyzed, published online by NASA (e.g. https://fireballs.ndc.nasa.gov/). For each meteor, the time of observation, velocity, beginning and ending height, Tisserand parameter, and orbital elements are available.

The third system also operates in southeastern Arizona but focuses on the detection of faint meteors (fainter than 3rd magnitude). This collaboration is with the GMN (Global Meteor Network), which provides information on the radiant, orbital elements, brightness, and mass of each detected meteor. The results are public and available at https://globalmeteornetwork.org/data/plots/. The Vatican Observatory contributes 3 cameras installed in parallel with the Asgard system.

Constraining the Gas Mass of Protoplanetary Disks: From CO to Multi-Molecular Approaches

Miss Amina Diop[1], Dr. Ilse Cleeves[1], Dr. Dana Anderson[2], Dr. Jamila Pegues[3], Dr. Adele Plunkett[4]

[1]University of Virginia. [2]Earth and Planets Laboratory, Carnegie Institution for Science. [3]Space Telescope Science Institute. [4]National Radio Astronomy Observatory

Abstract

Thousands of planetary systems have been discovered, each characterized by unique orbital patterns and chemical compositions. The next logical step is to investigate how the birthplace of planets, protoplanetary disks, evolve into these diverse systems. However, the gas mass of disks, one of the most important properties determining the outcome of planet formation, remains poorly constrained due to the difficulty in detecting H2, the main gas constituent. CO has been often used as a mass proxy, but its chemistry is very sensitive to the disk physical conditions. I will first present the results of our study where we developed a novel approach combining chemical modeling and machine learning to understand how physical conditions, i.e., gas temperature, UV field, cosmic ray and X-ray ionization rates, gas density impact CO chemistry. Our findings reveal a complex interplay between CO and disk conditions, suggesting a tendency toward CO depletion and highlighting its unreliability as a gas-mass tracer. These findings agree with previous more modeling intensive and computationally expensive studies, demonstrating the usefulness of machine learning in efficiently unraveling complex chemical processes. Additionally, I will share results from our ongoing efforts to constrain gas masses using multi-molecular approaches, recently proven to be more robust than single-molecule attempts. These efforts utilize the rich molecular data collected by the largest ALMA disk chemical survey, the Disk-Exoplanet C/Onnection (DECO) in tandem with machine learning techniques and physical-chemical disk models to identify the best molecular combinations tracing gas masses.

Simulation of the Planetary Mass-Radius Relation Using Machine Learning

Ailar Alizadehsabegh

University of Tabriz, Tabriz, Iran

Abstract

The objective of this study is to develop an appropriate model for estimating the radius of planets using the fewest features possible from spectroscopic observations. Investigations on the mass-radius relationship using various methods have been published. Our intention is to provide an optimal model for the mass-radius relationship, regardless of the type of planet. We created a sample in machine learning studies of the planetary mass-radius relation with 792 planets, including exoplanets, eight solar system planets, and Pluto, for this study. A number of different features were tested, and four features that showed the most impact on the model, including planetary mass, equilibrium temperature of the planet, host star's radius, and stellar mass, were selected. Considering that different machine learning models were used in previous studies, we tried the 19 most common regression models. According to the metrics, eXtreme Gradient BOOSting (XGBoost) and Random Forest (RF) produced the best results. We selected some exoplanets to examine in the model, including gaseous planets and an exosolar system with Earth-like planets. The radius estimation in the model of this study was compared with the radii declared or calculated by other studies and methods, which shows that the model performs well. The model described in this study is more appropriate for estimating the radius of planets since it has a greater number of samples, fewer features, reduced errors, and performs across the entire range of planet radii.

A possible mechanism for the origin of the dwarf planets in the Kuiper belt

Anatoliy Kazantsev

Taras Shevchenko National University of Kyiv

Abstract

The distributions of the orbital elements of most of bodies of the “hot” component in the Kuiper belt (KB) were analyzed. The distributions’ shapes indicate that all those bodies (including four dwarf planets) could have arisen as a result of the destruction of one massive body (the Kuiper belt planet, KBP). The separation velocities of the fragments were determined mainly by the linear velocities of the parts of the KBP at different depths and latitudes. The maximum separation velocity corresponded to the linear velocity on the surface of the KBP near the equator and could be 2.4 km/s. The spin axis of the KBP was tilted at a little angle to the ecliptic plane and at the destruction moment it was directed towards the Sun. The performed model calculations of the KBP destruction show that the resulting distributions of the model fragment orbits almost completely correspond to the distributions of the real orbits of the KB bodies.

This model predicts, then the spin axes of the fragments should be inclined at small angles to the planes of their orbits. The fragments with not large orbit inclinations may be inclined at small angles to the ecliptic plane. The spin axes of the dwarf planets Pluto (i = 17°) and Haumea (i = 28°) are inclined to the ecliptic plane at angles of 23° and 10°, respectively. The spin axis of the dwarf planet Eris (i = 44°) is inclined to the plane of it orbit at an angle of 12°.

Variations in Background Radiation over Earth's History

Dr James Welsh[1,2], Dr Andrew Karam[3]

[1]Loyola University Stritch School of Medicine. [2]Edward Hines Jr VA Medical Institution. [3]National Urban Security Technology Laboratory

Abstract

Our radioactive Earth is incessantly irradiated by space radiation. But this cosmic bombardment has been inconstant, and Earth's inherent radioactivity has decreased over geologic time. Here, we analyze varying sources of natural background radiation:

1. Primordial radionuclides
2. Cosmogenic radionuclides
3. Cosmic rays plus extraterrestrial gamma rays

As lithophilic elements, uranium, thorium and potassium-40 were partitioned into Earth's earliest felsic continental crust. The activity of these primordial radionuclides (and their progeny) has decreased monotonically over time. Dose from biospheric ^{14}C varies slightly and irregularly over time. Dose from cosmic rays and cosmogenic radioisotopes is relatively consistent but varies with changes in atmospheric chemistry/thickness, solar activity, geomagnetic field strength and galactic cosmic ray flux. Earth has also been intermittently irradiated through gamma ray bursts and other sporadic astrophysical incidents. Such infrequent events may have briefly escalated dose by a few orders of magnitude and transiently depleted stratospheric ozone. Episodic geophysical and solar events such geomagnetic excursions/reversals, grand solar minima, and Miyake events have also intermittently increased the biosphere's background dose. Furthermore, through fixation of radiogenic damage, the rise in free molecular oxygen after the Great Oxidation Event dramatically increased the radiobiological effectiveness of low-LET environmental radiation.

Life arose in the Archean when background radiation was >10x higher than today. Multicellular organisms evolved in a high radiation background and now possess effective means of coping with radiogenic molecular damage though the DNA damage response. Earth's long, variable radiation history is reflected in life's effective molecular means of managing radiation damage.

Equivalence between simple multilayered and homogeneous laboratory-based rheological models in planetary science

Dr. Yeva Gevorgyan[1,2], Dr. Isamu Matsuyama[3], Dr. Clodoaldo Ragazzo[1]

[1]Instituto de Matemática e Estatística, Universidade de São Paulo, R. do Matão, 1010, São Paulo, SP 05508-090, Brazil. [2]CEMSE Division, King Abdullah University of Science and Technology (KAUST), Thuwal, Saudi Arabia. [3]Lunar and Planetary Laboratory, University of Arizona,1629 E University Blvd, Tucson, AZ 85721, USA

Abstract

We investigate under which circumstances the tidal response of a stratified body can be approximated by that of a homogeneous body. We show that any multilayered planet model can be approximated by a homogeneous body, with the same dissipation of tidal energy as a function of the excitation frequency, as long as the rheology of the homogeneous model is sufficiently complex. These results highlight the fact that the two models cannot be distinguished from each other only by the measurement of the second degree tidal Love number and quality factor, and that we do not need the complexity of the multilayer planet model in order to estimate its tidal dissipation. The methodology promises a great simplification of the treatment of multilayered bodies in numerical simulations because the treatment of a homogeneous body – even with a complex rheological model – can be computationally better handled than that of a multilayered planet.

Ethanolamine stability in simulated space conditions

Dr John R. Brucato[1], Dr. Sole Biancalani[2], Dr. Victor M. Rivilla[3]

[1]INAF - Arcetri Astrophysical Observatory, Firenze Italy. [2]University of Trento, Trento Italy. [3]Centro de Astrobiologia (CAB, INTA-CSIC), Madrid Spain

Abstract

Laboratory experiments on the interactions between complex organic molecules, interstellar dust and UV radiation are crucial to understand the physico-chemical mechanisms that lead to the synthesis of organic molecules, and to search for new species not yet observed in the interstellar medium ISM gas phase. Ethanolamine ($NH_2CH_2CH_2OH$) is an organic molecule of great astrobiological interest, proposed as a precursor of phospholipids, the main constituents of cell membranes, and of glycine, the simplest amino acid. This molecule, already detected in the Almahata Sitta meteorite, has recently been observed in the ISM in the molecular cloud G+0.693-0.027. Its presence in the gas phase suggests that ethanolamine, once formed on dust grains, is involved in solid-state chemistry. The aim of this work was to study in the laboratory the physico-chemical properties of ethanolamine in simulated astrophysical condition, in order to understand its stability and role in surface chemistry in the ISM. We irradiated the icy sample at 10 K *in situ* with the UV-enhanced Xenon lamp, simulating the radiation of solar-type stars, and also the secondary UV emission due to cosmic rays inside dense molecular clouds. We performed the analyses by adsorbing the molecules onto nanometric fluffy grains of amorphous olivine, to study their catalytic role of dust. Our results provide support for understanding existing observational data and indicate possible targets for future observations. Furthermore, they improve our knowledge of the role of the grain surface in the enrichment of chemistry in space.

Exploration of habitable worlds in the solar system

Dr Athena Coustenis

Paris Observatory, CNRS, PSL University

Abstract

Besides Mars, currently under extensive exploration (Mars Express, ExoMars, Hope, Mars2020/Perseverance, Tianwen-1 etc) and remains an object with many unknowns about its past [1], the satellites of the gas giants Jupiter and Saturn, situated beyond the snow-line and the traditional "habitability zone" [2], have been revealed as potential habitats by missions like Galileo, Cassini-Huygens and Juno, presenting promising conditions for habitability [3]. Jupiter's Europa and Ganymede show indications of harboring internal liquid water oceans while Europa may be in direct contact with a silicate mantle floor and kept warm through time by tidally generated heat [4]. Around Saturn, Titan, Mimas and Enceladus, were found to possess internal liquid water oceans and sometimes organic chemistry [3]. The icy satellites provide a conceptual basis for new theories of habitability.

These bodies will be further investigated in the future by missions to the red planet (such as ExoMars 2028 and Mars Sample Return) but also by exploring the icy moons around the giant planets. Future exploration of the Galilean satellites includes missions like ESA's JUICE, [4] (launched in 2023, arrival in 2030) and NASA's Europa Clipper [5] to launch in 2024. For Titan, NASA selected the Dragonfly mission [6].

Evolution of Carbonaceous Asteroids as a Factory of Prebiotic Molecules

Shogo Tachibana

University of Tokyo

Abstract

The JAXA's Hayabusa2 spacecraft returned about 5 grams of surface materials from C-type near-Earth asteroid (162173) Ryugu in December 2020 (Tachibana et al. 2022).

The Ryugu samples show close relations with CI chondrites chemically, isotopically, mineralogically, and petrologically (e.g., Yokoyama et al. 2022; Nakamura T. et al. 2022; Okazaki et al. 2022; Noguchi et al. 2023; Yabuta et al. 2023; Naraoka et al. 2023). Among more than 20000 organic molecules, prebiotic molecules such as amino acids, uracil, and nicotinic acid have been identified (e.g., Naraoka et al. 2023; Parker et al. 2023; Oba et al. 2023). The presence of CO2-bearing fluid inclusions in pyrrhotite indicates that Ryugu's parent planetesimal formed in the outer region of the Sun's protoplanetary disk (Nakamura T. et al. 2022). Because the main belt is dominated by C-type asteroids, Ryugu-like planetesimals were likely to have been transported from the outer to the inner Solar System, and Ryugu's siblings may have brought water and organics to the early Earth (e.g., Yabuta et al. 2023; Naraoka et al. 2023).

In this presentation, we will discuss what we have learned from Ryugu about its formation and evolution of Ryugu as a factory of prebiotic molecules.

Rogue worlds and black holes in the era of Roman

William DeRocco

University of California, Santa Cruz

Abstract

During the chaotic early stages of system formation, gravitational scattering is expected to efficiently eject a large number of planets and planetesimals over a wide range of masses. In the terrestrial-mass range, these ejecta constitute "free-floating planets" (FFPs) and are expected to outnumber their bound counterparts. Despite the large abundance, FFPs are a difficult target for observation. The only existing observational technique sensitive to these objects is gravitational microlensing. While ground-based observatories have produced tantalizing hints of this population, our understanding of these worlds will be transformed with the launch of the Roman Space Telescope in 2026, whose Galactic Bulge Time Domain Survey will usher in a new era of discovery through microlensing. In this talk, I will discuss how by leveraging the high-statistics observations that Roman will make, we will be able to make our first direct measurement of the mass function of this enigmatic population, as well as its unique implications for models of planetary system formation and, potentially, for our understanding of dark matter and the early universe. Furthermore, I will discuss how we are engaging the broader astronomical community at all career stages on becoming involved in microlensing analysis in advance Roman's launch.

A Dynamical Synthesis of Planetary Systems

Prof. Malena Rice

Yale University

Abstract

Over recent decades, complementary lines of evidence have each offered independent constraints on the underlying mechanisms shaping planetary system architectures. My dissertation progresses at the intersection of subfields, drawing from both solar system and exoplanet studies to develop a cohesive picture of planetary system evolution. My work leverages dynamics to synthesize the joint imprints of planetary evolution on stars, planets, and minor planets. First, I demonstrated that stellar occultation events can provide sufficiently precise positional measurements of solar system asteroids to constrain the presence of neighboring masses, including the predicted “Planet Nine” in the distant solar system. I then developed a novel algorithm to directly search for distant solar system objects using NASA’s Transiting Exoplanet Survey Satellite, demonstrating a new use case for the survey. In parallel, I showed that the long-period Neptune-sized exoplanet population suggested by protoplanetary disk images can efficiently eject neighboring minor planets, accounting for the high rate of observed interstellar objects passing through the solar system. Lastly, I spearheaded the SOLES survey to extend the sample of measured stellar obliquities in long-period exoplanet systems. My analysis of the stellar obliquity distribution provided evidence that hot Jupiter systems are largely shaped by post-disk dynamical interactions.

[6]School of Natural Sciences, University of Galway, University Road, H91 TK33 Galway, Ireland

Abstract

In this study, we present K-band imaging and polarimetry of the young disk system, LkCa 15. Leveraging near-simultaneous reference star difference imaging,or "star-hopping," we unveil the true intensity of the disk without the interference of self-subtraction effects for the first time. Our primary objectives are to identify potential new giant planets beyond 0.1'' separations and to analyze the disk's morphology to understand its interactions with the existing planets. Through radiative transfer modeling, we align the near-infrared imaging with polarimetric data and further integrate sub-millimeter imaging data from ALMA. We model our LkCa 15-protoplanetary disk using three grain components consisting of submicron, micron, and sub-millimeter sized grains. Our results indicate a highly flared region in the inner part of the disk with notable features with a very strong forward scattering.We also analysed the K-band inverse polarimetric map, no new planets were found outside of a 12 au separation.However, based on contrast curve estimates, we have established an upper mass limit for potential companions that might be present in LkCa 15. In conclusion, we are able to constrain the disk morphology using the three component radiative transfer modelling and also estimate the upper limits for the companion mass that might be present in this system at different separations from the host star.

[4]LESIA-Observatoire de Paris, Université PSL, CNRS, Sorbonne Université, Université de Paris, 5 place Jules Janssen, 92190 Meudon, France.

Abstract

The anthraquinone pigment parietin is a secondary lichen substance providing UV-shielding properties that is produced by several lichen species. In our study, we extracted the secondary metabolite from air-dried thalli of *Xanthoria parietina*. The objectives of this work were to analyse the absorbance of parietin using UV-VIS spectrophotometry and its photodegradability under UV radiation thought *in situ* reflectance FTIR spectroscopy. This analysis aims to determine the extent to which parietin may provide photoprotection. This enables us to relate parietin photo-degradability and the lichen UV tolerance in its native terrestrial habitats, as well as in extreme environments relevant to astrobiology, such as Mars. Crystals were UV irradiated for 5.59 hours under N_2 flux. Then, we evaluated significant degradations in the bands at 1614, 1227, 1202, 1160, and 755 cm^{-1}. Considering *Xanthoria parietina* resilience in extreme environments like space and Mars-simulated ones, we emphasize the UV photo-resistance of parietin and its significance in astrobiology as a protective substance against UV radiation and potentially being a bio-hint.

The Aligned Orbit of TOI-2533 b, a Transiting Brown Dwarf Orbiting an F8-type Star

Thiago Ferreira dos Santos[1], Malena Rice[1], Xian-Yu Wang[2], Songhu Wang[2]

[1]Yale University. [2]Indiana University Bloomington

Abstract

Brown dwarfs comprise an intermediate class of objects between the giant planet and low-mass star regimes. As such, the orbital orientations of brown dwarfs orbiting stellar hosts provide insights into the formation channels that delineate these neighbouring classes of astronomical objects. We present an analysis of the Rossiter-McLaughlin (RM) effect across the transit of TOI-2533 b, a brown dwarf on a moderately eccentric ($e = 0.2476 \pm 0.0090$) and wide-separation ($a/R_* = 13.34 \pm 0.30$) orbit around an F8-type star, using data from the NEID/WIYN spectrograph in combination with archival photometry and radial velocity observations. Spin-orbit analyses of brown dwarfs are relatively rare, and TOI-2533 stands out as the fifth brown dwarf system with a measured stellar obliquity. We derive a sky-projected stellar obliquity ($\lambda = -7 \pm 14$ deg) for TOI-2533 b, consistent with alignment. Our joint model also indicates that TOI-2533 b falls within the minimum mass range for sub-stellar objects undergoing hydrogen-burning ($M_b = 74.9 \pm 5.3\ M_{Jup}$), and considering its equilibrium temperature ($T_{eq,b} = 1095 \pm 17$ K), we propose that it qualifies as a T-type brown dwarf. We conclude that TOI-2533 b is fully consistent with formation in a spin-orbit aligned disk without primordial misalignment, potentially during the second collapse phase of a molecular cloud's fragmentation.

Graph Algorithmic Thinking for the Waw! Signal. The first contact.

Graph Algorithmic Thinking for the Waw! Signal. The First Contact. Gizo Vashakidze

Institute of Ecology, Faculty of Exact and Natural Sciences at Iv. Javakhishvili Tbilisi State University

Abstract

A novel feature of the present work consists of a unique approach. When considering the Wow! signal, not only the 6 radio signals received on channel #2 are taken into account, but also the total content of the 12 high-intensity signals received on six different channels, as a result of which we got an infographic image. (New encoding method) The infographic shows a brief description of the solar system. Also, the distance from the sun to the star is also recorded—about 20 light-years. There are several stars at this distance from the Sun. The researchers from the Big Ear radio telescope report that at the moment of picking up the signal, the scanning of the sky took place towards the constellation Sagittarius. The binary pair, J. Herschel 5173 AB, is located at approximately the same distance. According to the calculations of astronomers, the mentioned binary pair of stars and the Sun are approaching each other (Bobylev, 2010). The infographic representation of the radio signal displays the same information. The stellar convergence can be considered the motivation for beginning written communication. The radio signal displays an image of a man and a woman. The outlines of both pictures are similar to the „Profile Picture" template that you often see on the Internet. In 1973, humans did the same; a picture of a man and a woman was sent into space. (Pioneer plaques) Also, neighboring civilization propose an agreement for two-way communication using the coding method present in the Wow! signal.

Ice on comets : Lessons learned from the Rosetta mission

Prof. Sonia Fornasier

LESIA, Université Paris Cité, Observatoire de Paris, Université PSL, CNRS, Sorbonne Université, 5 place Jules Janssen, 92195 Meudon, France. Institut Universitaire de France (IUF), 1 rue Descartes, 75231 PARIS CEDEX 05

Abstract

Ice is one of the main constituents of cometary nuclei but it is rarely observed exposed on their surfaces, as evidenced by images from Giotto, Deep Space 1, Stardust, Deep Impact-Epoxy and Rosetta, the missions dedicated to in-situ cometary investigation. ESA's Rosetta mission, which orbited comet 67P/Churyumov-Gerasimenko (hereafter 67P) for more than two years, provided a unique opportunity to study the morphology, composition and activity of 67P's nucleus, and their evolution over time at different heliocentric distances.

A dedicated analysis of exposed water ice revealed that it represents only 0.1% of the total surface of 67P, confirming that cometary nuclei are dominated by refractory dark terrains. The vast majority of identified ice exposures on 67P are typically on the order of a meter or sub-meter in size, demonstrating the need for high spatial resolution to identify ice on cometary nuclei. Although rarely exposed, several lines of evidence indicate that ices are abundant just below the surface: cliffs collapse or outbursts often exposed subsurface layers enriched in water ice, with local water ice abundances up to 75%; spectacular diurnal and seasonal color variations have been observed on 67P nucleus, associated with the sublimation and recondensation cycle of water ice with varying temperature over day-night/seasons. The main findings on the 67P nucleus composition, especially in terms of volatiles, and the lessons learned from the Rosetta mission on ice detection, size distribution, and lifetime will be presented.

Recent results of NEO space missions and perspectives

Dr. Patrick Michel

Université Côte d'Azur, Observatoire de la Côte d'Azur, CNRS, Laboratoire Lagrange, France

Abstract

The past years have produced a large number of new results and science advances in the field of NEO studies thanks to space missions that returned samples (JAXA Hayabusa2, NASA OSIRIS-REx) or performed a deflection test (NASA DART). They also revealed the complex geology of these objects and their counter-intuitive behavior in their low-gravity environment. So far, NEOs showed us the behavior of bodies having a very weak cohesion, while solid rocks are present on the surface and numerical models indicate that they are sensitive to unexpected low cohesion levels of the order of 0.1 Pa. These bodies are thus more complex than we could anticipate, showing the high value of space missions visiting them. The ESA Hera mission will allow checking the simulation predictions of the DART impact outcome. In April 2029, nature offers us a laboratory to explore the response of small asteroids to external forces, with the close passage of Apophis to Earth. NASA APEX will visit Apophis a few days after this close passage and mission studies are ongoing to visit the asteroid before and during this passage, offering a great synergy with APEX. The Hayabusa2# mission will also rendezvous with a 30 m-size fast rotator NEO in 2031, allowing us to investigate the properties of an object, whose size is similar to that of the bolide that exploded over Tunguska in 1908. Thanks to these missions and possibly other ones, our understanding will again improve drastically, since so far, all missions challenged our knowledge.

Potential detections of M-dwarf rocky planet atmospheres and a trend in atmosphere occurrence

Dr. Megan Weiner Mansfield[1,2], Dr. Jacob Bean[3], Jegug Ih[4], Dr. Eliza Kempton[4], Dr. Edwin Kite[3], Qiao Xue[3], Dr. Michael Zhang[3]

[1]University of Arizona. [2]NHFP Sagan Fellow. [3]University of Chicago. [4]University of Maryland

Abstract

One of the most exciting opportunities enabled by JWST is the characterization of atmospheres on terrestrial planets orbiting M dwarfs (M-Earths). However, transmission spectroscopy of M-Earths with JWST has been ambiguous due to challenges such as stellar contamination. We discuss the technique of thermal emission observations during secondary eclipse, which is a rapid way to detect M-Earth atmospheres with JWST without encountering issues of stellar contamination.

We present thermal emission observations of three hot M-Earths (GJ 367b, Gl 486b, and GJ 1132b) observed with JWST/MIRI+LRS between 5-12 microns. A phase curve of GJ 367b, the hottest planet in this sample, shows a maximally hot dayside and zero heat redistribution, consistent with an airless body. However, secondary eclipses of the cooler planets Gl 486b and GJ 1132b show colder daysides than expected for a bare rock. These detections represent the strongest evidence yet of M-Earth atmospheres. When combined with other JWST M-Earth results, we find a trend suggesting that planets at irradiation temperatures below 800 K retain atmospheres, while hotter planets are airless.

[11]Royal Institute of Technology SE

Abstract

The interaction of the solar wind with planetary magnetic field creates a magnetic cavity called the magnetosphere. Deep inside this magnetic structure, the trapping of 10's of keV up to 10's (100's) of MeV electrons (ions) forms the radiation belts. Radiation belts exist at Jupiter, Saturn, Uranus and Neptune. At Jupiter, the electron belt is the source of a strong magneto-bremsstrahlung emission at frequencies of ~0.05 - 8 GHz. Although the detection of this radio emission presented the first evidence of a harsh radiation environment at Jupiter in the late 1950s, its spatio-temporal variations on different timescales remain unexplained more than 60 years later. We present our on-going multi-frequency investigation of Jupiter's electron-belt emission from multiple interferometers (VLA, MeerKAT, GMRT, ATCA, LOFAR). We demonstrate how multi-data-set analyses at 0.05 - 8 GHz reveal the contribution of trans-to-ultra-relativistic electrons trapped in different magnetospheric regions to Jupiter's radio spectrum. We emphasize how our improved understanding of the dynamical response of energetic electrons to magnetospheric and heliospheric environments can provide new interpretations of on-going remote sensing observations at Jupiter, while yielding new information on the radiation environment that JUICE and Europa Clipper will encounter at larger distances. We finally discuss our computational effort to model the electron-belt emission at Saturn, Uranus and Neptune and subsequent implications for future missions at the ice giant planets.

Juno Results on the Origin and Evolution of Jupiter

Dr Scott Bolton[1], Juno Science Team[2]

[1]SwRI. [2]Cornell, Caltech, U. Michigan, JPL, UC Berkeley, Observatory Cote D'Azur

Abstract

Results from the Juno investigation of Jupiter has challenged our understanding of Jupiter origin and evolution. As the archetype of giant planets, the study of Jupiter provides knowledge needed to understand the origin of our own solar system and the planetary systems being discovered around other stars. No other object in the solar system can tell us more about the origin of planets than Jupiter. The mass of Jupiter's solid core and the abundance of heavy elements in the atmosphere discriminate among models for giant planet formation. Measurements by Juno of Jupiter's gravity field suggest Jupiter's core is diffuse, extended and contains compositional gradients. These new results require new models of Jupiter's formation and evolution. The gravity science results on the measurement of J4 coupled to current estimates on the Hydrogen and Helium equation of state suggests Jupiter's interior composition has very low metallicity, potentially solar or even sub-solar. This is inconsistent with measurements of the atmosphere by both Juno and the Galileo probe which indicate the atmospheric composition is of higher metallicity (3-4x solar). The combined results from Juno provide new constraints on theories of Jupiter's formation and evolution and giant planets in general. A summary of Juno's results relevant to Jupiter's formation and evolution will be presented along with a discussion of theoretical implications on Jupiter, and giant planets both within our solar system and beyond.

Abstract

The planets outside of our solar system are known as exoplanets. Finding exoplanets is a major area of research in the hopes of discovering a habitable, earth-like planet. There are various analytical methods related to the detection process, Like the radial velocity method, the transit method, etc. Initially, people use these methods to classify exoplanets, but it is a time-consuming process. As things are done manually, there is an issue related to accuracy. The merging of machine learning (ML) and neural network techniques has significantly advanced the area of exoplanet discovery in recent years. Researchers and space agencies are working with TESS, K2, and Kepler data and applying that to convolution neural network models. The accuracy of the suggested model is being enhanced through multiple adjustments and tuning of hyperparameters. In this area, several AI models have already been generated. So, we have used the powerful Transformer model to handle time series data due to its ability to capture long-term dependencies, combining that with the recurrence plot technique. The model was applied to massive data, resulting in an impressive accuracy rate of 95.85% and a precision rate of 94.92%. This impressive accuracy indicates the model's reliability in classifying cases and distinguishing between exoplanets and non-exoplanet objects. It also has a precision rate of 94.92%, indicating its ability to accurately predict exoplanet presence.

Abstract

Juno's use of its low-light Stellar Reference Unit (SRU) star camera as a high-resolution visible wavelength science imager has opened unprecedented opportunities for exploration of Jupiter's enigmatic ring system and a search for lightning on Jupiter's dark side. SRU imaging of Europa's night side (illuminated by Jupiter-shine) in 2022 yielded the Mission's highest resolution image of the icy moon, enabling significant improvements to the geomorphologic mapping of the surface and revealing sites of potential present day surface activity (providing high quality baselines for the upcoming Europa Clipper and JUICE missions). Juno's recent flybys of Io in December 2023 and February 2024 presented additional opportunities for low-light high-resolution SRU imaging of the night side of this highly volcanic moon. Our presentation will discuss the latest results from Juno's innovative SRU imaging campaigns.

Results of Observations of the Jovian System by Juno and a Network of Earth-Based Astronomical Observing Stations

Glenn Orton[1], Scott Bolton[2], Stephen Levin[1], Thomas Momary[1], Shawn Brueshaber[3], Emma Dahl[1], Juno Science Team[2]

[1]Jet Propulsion Laboratory, California Institute of Technology. [2]Southwest Research Institute. [3]Michigan Technological University

Abstract

The Juno mission to the Jupiter system has promoted and coordinated a network of Earth-based astronomical observations, both Earth-proximal and ground-based facilities, to extend and enhance its own observations. The spectral region and timeline of all of these observations are summarized in the web site: https://www.missionjuno.swri.edu/planned-observations. These include Juno's approach phase, e.g. observation of Jovian auroral phenomena and measurements of Jovian synchrotron radiation from the Earth simultaneously with the measurement of properties of the upstream solar wind. Observations of significance to the magnetosphere measure the mass loading from Io by tracking its volcanic activity and its torus opacity. Measurements of Jupiter's neutral atmosphere include observations of reflected sunlight from the near-ultraviolet through the near-infrared and thermal emission from 5 μm through the radio region. These measurements relate properties of the deep atmosphere, a major focus of Juno, to the state of much higher atmospheric levels. These observations access spectral regions not covered by Juno, expand Juno's spatial range, and track the evolution of features measured only once by Juno. We summarize the results of observations made by Juno and the supporting campaign during the primary and extended missions. Observations in the extended mission include support for close encounters of Juno with the Galilean satellites. Besides a global network of professional astronomers, the Juno mission also benefited from the enlistment of a network of dedicated amateur astronomers who provided a nearly continuous survey of the evolution of features observed by Juno's instruments.

The Development of a Superconducting MKID High Resolution Multi-Object Spectrometer Testbed for the Detection and Characterization of Exoplanets.

Ronald Lopez[1], Benjamin Mazin[1], John Bailey[2,1], Crystal Kim[1]

[1]University of California, Santa Barbara. [2]California Institute of Technology

Abstract

Conventional high-resolution spectrographs are typically designed to take detailed spectra of single targets or of a very limited field of view. On the other hand, multi-object spectrographs are designed to acquire spectra of multiple targets simultaneously at the expense of spectral resolution, wavelength coverage, and/or instrument cost. The inherent energy resolution of superconducting microwave kinetic inductance detectors (MKIDs) can be used to eliminate the need for a cross-dispersing element in a high-resolution spectrograph, freeing up valuable detector space that can be allocated to the spectra of multiple objects. This work lays the foundation for the development of a new class of high-resolution multi-object spectrographs (HRMOS) without the need to compromise resolution or coverage. A future, fiber-fed MKID HRMOS for the extremely large class of telescopes will be able to sample a comprehensive region around a star with an R~100,000 to simultaneously detect and characterize exoplanet atmospheres using high-dispersion coronagraphy.

A survey of comets in the vicinity of Jupiter

Gonzalo Tancredi[1], Mario Hierro[1,2], Silvia Martino[1], Martín Cavarozzi[1], Ernesto Elenter[1], José Furtado[1], Mariana Gutiérrez[1], Silvia Hernández[1], Mateo Muñoz[1], Nicolás Pan[1], Juan Roberto Varela[1], Miguel Alarcón[3], Javier Licandro[3], Antonio Maudes[2], Miquel Serra-Ricart[2,3]

[1]Depto. Astronomía, Fac. Ciencias, Udelar, URUGUAY. [2]Light Bridges, SL, Spain. [3]Instituto de Astrofisica de Canarias, Spain

Abstract

Based on our dynamic analysis of Jupiter Family Comets (JFCs) in 1991, it was proposed that Jupiter's vicinity presents the highest likelihood of encountering a comet (Tancredi & Lindgren 1992). A survey to detect comets approaching Jupiter was recommended. Following this advice, the Shoemaker-Levy team directed their NEO survey telescope near Jupiter for the first time in March 1993 and discovered the renowned P/Shoemaker-Levy 9, which was undergoing a temporary capture by the planet. Concurrently, we also observed it during our survey around the same time (Tancredi & Lindgren 1994).

It has been 20 years since then, and survey technologies have significantly advanced. In November 2023, Jupiter was at opposition and near perihelion, providing an excellent opportunity to replicate the survey using the 80cm Light Bridges' telescope equipped with a large-format CCD (151 Mpx). We covered a sky area of 7.6degx6.6deg (50 deg^2) across 143 fields. Each field was captured in sequences of four images with an interval of ~5 minutes between shots, and these sequences were repeated on subsequent nights. By aligning the images based on Jupiter's motion, we enhanced detection capabilities. In December 2023, we acquired a new set of images for follow-up, yielding sufficient data to identify and calculate the orbits of new objects.

In this report, we share the preliminary findings of our survey. Despite not identifying any new objects approaching Jupiter, we will be able to establish an upper threshold for the JFC population and investigate the potential progenitors of recent impact flashes on Jupiter.

Subglacial Habitability from the Solar System to Exoplanets

Prof Amri Wandel

The Hebrew University of Jerusalem

Abstract

The Habitable Zone (HZ) is defined as the circumstellar region where liquid water can exist on a planetary surface. This definition of habitability may however turn out too strict, as even on Earth life strives under the ice cover of the north polar cap. Large quantities of liquid water are present under a relatively thin ice cover on bodies in our Solar System like Enceladus and Europa. Similarly, subglacial liquid water may be expected in exoplanets orbiting their host star outside of the HZ. Considering subglacial liquid water Wandel (2023) showed that the conservative HZ can be significantly extended. Exoplanets and satellites with geothermal heat sources can maintain liquid water outside of the conservative HZ under an ice cover, although their surface temperature is well below freezing. The HZ may be extended inwards for tidally locked planets, where the atmospheric water vapor can be transported to the night-side and condense as lakes (for intermediate atmospheric heat transport between the day and night sides) or as ice sheets (for low heat transport). In the latter case, the inner boundary of the extended HZ strongly depends on the degree of heat transport.

Exotic Red Flare on the Stars as Exo-Asteroid Manifestations

Dr Mansur Ibrahimov

Institute of Astronomy, Moscow, Russia (INASAN)

Abstract

Exo-world population is currently presented by 2 type of objects – exo-planets and exo-comets. To the date, more than 5000 exo-planets were discovered using spectroscopy (wobbling effect) and photometry (transiting effect), and more than 500 exo-comet observed as so called FEB-events (Falling Evaporating Body lines observed only spectroscopically). A question is: could exo-asteriods, the 3rd type of population, be discovered using existing observational methods ? A talk's answer is: yes, they can be discovered and they'd already been observed using IR/optic photometry. It is argued that a manifestation of an exo-asteriod activity is so called "red flare" on a star. For the first time, the talk brings together and presents practically all the observed red flares in IR/optic photometry. Exotic red flares are interpreted as collisional interaction and subsequent disintegration of the exo-asteroids accompanied by a huge (up to 10^{39} erg in optic) and long timescale (about of hours) energy production emitted mostly in IR and a red part of optical spectra. In contrast to well-studied "blue flares" on M dwarfs (flares on UV Cet-type stars), the red flares exhibit a red maximum in magnitude, red colors in optic, and a "red" distribution of flare amplitudes. So far, the red flares had already been observed in space IR missions (2 events), in several normal stars (6 events), in several systems with compact objects (tens of events), and in available star-flare statistical studies (hundreds of events). All the mentioned red flare events are briefly compared and analyzed in the talk.

Probing the Origins of Biomolecular Handedness with SKA Surveys for Sugar and Amino Acid Enantiomers

Miss Pallavi Kajrekar

Royal Astronomical Society. The University of Edinburgh

Abstract

The sugars and amino acids that make up terrestrial life exhibit exclusive handedness, with only D-sugars and L-amino acids incorporated into biology. The origins of this selective chirality remain unknown. As the world's largest radio telescope, the Square Kilometer Array (SKA) is set to provide unrivaled sensitivity for interstellar molecular surveys; this project will exploit SKA's capabilities for sensitive, wide-bandwidth observations to search for enantiomeric excesses in the simplest sugar (glyceraldehyde) and amino acid (alanine/glycine) toward galactic center clouds. The detection of both enantiomeric forms in interstellar space would demonstrate that abiotic synthesis yields racemic mixtures, implicating further chiral selection on planetary surfaces. Null detections may indicate asymmetric interstellar chemistry, providing astrophysical insight into the intriguing origins of biomolecular homochirality.Flux ratios of D- over L-enantiomers can further quantify any asymmetry, distinguishing interstellar versus planetary origins of chiral asymmetry essential for terrestrial biology.

Detection of Complex Organic Molecules in the protoplanetary disk of V883 Ori

Mr. Abubakar Fadul, Dr. Kamber Schwarz

Max Planck Institute for Astronomy

Abstract

The study of protoplanetary disks provides invaluable insights into the processes governing planetary formation and the chemistry of early solar systems. Here, I present observations of the protoplanetary disk surrounding the young stellar object V883 Ori, revealing the presence of complex organic molecules (COMs). V883 Ori is an FUor object in the Orion A L1641 molecular cloud. Given that the COMs were frozen out on the dust grains, we took advantage of the sudden increase in disk temperature caused by the outburst due to an increased accretion rate to detect these molecules. Previous studies have already detected COMs in this source, but our spectral scan covers more lines, allowing us to place better constraints on the emitting temperature, and by extension, the abundance, of these species.

Utilizing high-resolution spectroscopy of Atacama Large Millimeter/submillimeter Array (ALMA) Band 7, we detect a rich molecular inventory encompassing species such as methanol (CH3OH), acetone (CH3COCH3), and acetaldehyde (CH3CHO), among others. The detection of these COMs in the disk of the V883 Ori protoplanetary disk suggests the existence of efficient chemical pathways even in the early stages of planetary system formation. Furthermore, the abundance and distribution of COMs in this environment may serve as crucial precursors for prebiotic chemistry, potentially influencing the emergence of life on nascent planets. Our findings underscore the significance of investigating the chemical complexity of protoplanetary disks and contribute to a broader understanding of the chemical evolution of protoplanetary disks and the conditions necessary for the emergence of life-bearing planets.

New candidate planetary companion to the radial velocity standard star HIP10301

Dr Amina Boulkaboul, Dr Yassine Damerdji

Center of Research in Astronomy, Astrophysics, and Geophysics, Algeria

Abstract

HIP10301 is a K2V star listed in the catalogue of radial velocity (RV) standard stars used in wavelength calibration of the Radial Velocity Spectrograph (RVS) on board of Gaia satellite. Two planets orbiting this star with periods of 14.18 and 53.75 days have been confirmed (Ahrer et al., 2021). This study aims to search for new companions to this target. To this end, we employed the minimum distance algorithm to derive the star's RVs. This method, as described in Boulkaboul et al. 2022, entails matching observed spectra from the HARPS instrument with theoretical templates of MARCS-AMBER atmosphere models. Applying the Zechmeister and Kürster (2009) periodogram to the RV dataset, measured from the 1-D barycentric-corrected and orders-combined spectra, unveiled the presence of the two confirmed planets, alongside a long-period signal of 3169 ± 330 d attributed to the star's magnetic cycle. This assumption is confirmed by similar detections in stellar activity indicators, such as the S-index (3228 ± 80 d) and Bisector Inverse Slope (2395 ± 442 d). Furthermore, another periodic signal with a period of 18.986 ± 0.019 days was identified. It is noteworthy that this period did not emerge in the RV dataset derived from the 2-D spectra, which lack barycentric correction, and instead yielded a yearly period, despite the final RVs being corrected to the barycenter. Conversely, correcting the spectra to the barycenter before RV measurement led to the disappearance of the yearly signal and the appearance of a peak at 18 days, rendering the hypothesis of this signal being planetary more plausible.

[5]Centre of Molecular and Environmental Biology (CBMA-UMinho, Portugal). [6]Simón Bolívar University (Venezuela)

Abstract

Most hypotheses locate the origin of life in an aquatic environment, emphasizing the importance of oceanic celestial bodies like Enceladus, Europa, and exoplanets in the search for extraterrestrial life. Thus, investigating analogous Earth's habitats is essential. One of them is tidal zones, an extreme environment where conditions of desiccation and exposure to ultraviolet radiation are common. These areas harbor marine tardigrades, known for their extreme resilience. Despite extensive study in various habitats, marine tardigrades remain relatively unexplored. Our research aims to improve the current level of knowledge through the study of marine tardigrades as models of extraterrestrial habitability, particularly concerning oceanic celestial bodies.

In this study, we collected several samples of *Caloplaca*, *Lichina pygmaea* and macroalgae of the genus *Ulva* at Portiño Beach (Galicia, NW Spain). After isolating individuals, six genera were identified: *Ramazzottius*, *Macrobiotus*, *Milnesium*, *Echiniscoides*, *Styraconyx* and *Batillipes*. Individuals of different ages as well as eggs were isolated. Morphological differences were also observed between taxa and between females and males in some genera. Individuals of *Echiniscoides* and *Ramazzottius* were selected to establish long-term cultures under laboratory conditions. We will present the results obtained, including observations on life cycles and resistance mechanisms.

Our study also aims to gather information on the response of marine tardigrades in active or resistant states to different stress conditions. In particular, we are investigating the influence of hypomagnetic conditions on this taxon, for which there are very few studies. To do this, we will compare the results obtained in the genera *Echiniscoides* and *Ramazzottius*.

"What If Earth Orbited TRAPPIST-1?

Prof. William Welsh, Mr. Jospeh Soliz

San Diego State University

Abstract

It took ~700 million years between the origin of oxygenic photosynthesis in cyanobacteria and the rise of oxygen in our atmosphere (the "Great Oxidation Event" or GOE). Oxygenic photosynthesis requires light in the "PAR" (Photosynthetically Active Radiation) wavelength range: 400-700 nm. TRAPPIST-1 is an M dwarf with Teff of only 2560 K. If Earth orbited TRAPPIST-1 at the same distance as TRAPPIST-1e, it would be in the habitable zone but the number of PAR photons would be 0.9% of what it receives from the Sun. If the rate of oxygen production is proportional to the number of PAR photons, it would take ~60-75 billion years for a GOE. But the linear assumption is poor: photoinhibition decreases photosynthesis at high incident flux and this reduces the timescale by a factor of ~2. Tidal locking provides another factor of 2. Extending the upper wavelength limit of the PAR out to just 750 nm doubles the number of photons. These factors lead to a timescale between the origin of oxygenic photosynthesis and a GOE of ~4-7 Gyrs; a Cambrian explosion would take ~15-26 Gyrs. However, non-oxygenic photosynthetic bacteria can use light out to 1100 nm, and for TRAPPIST-1 this provides over 50 times as many photons! Such bacteria would have a huge advantage and thus dominate over oxygen-producing cyanobacteria. We speculate that on such a hypothetical planet, a GOE would never occur, let alone a Cambrian explosion. Complex macro-cellular animal life would not exist. The real TRAPPIST-1e may have this same fate.

Dust in the solar system measured by the Juno spacecraft en route to Jupiter

Peter Jorgensen[1], John Jorgensen[1], John Connerney[2], Mathias Benn[1], Anja Andersen[3], Troelz Denver[1]

[1]Technical University of Denmark, Lyngby, Denmark. [2]Space Research Corporation at NASA GSFC. [3]University of Copenhagen, Denmark

Abstract

A star camera aboard the Juno spacecraft traveling from Earth to Jupiter serendipitously recorded the impact of interplanetary dust particles (IDPs) by imaging bits of the spacecraft ejected from the IDP impact sites. In essence, the Juno spacecraft, with its expansive ~60 m^2 of solar arrays, served as a dust detector with orders of magnitude more aperture than dedicated dust detectors specifically designed and flown to detect dust impacts. Consequently, Juno recorded many impacts by the larger (few to tens of micro-meters) and less numerous IDPs that populate the inner solar system, establishing for the first time their distribution and source (Jorgensen et al., 2020). This dust population, of the size responsible for the Zodiacal light, resides between the orbit of Earth and the 4:1 mean motion resonance with Jupiter, and explains the variation of Zodiacal light with ecliptic latitude if the dust introduced into the solar system with the inclination and eccentricity of the planet Mars. This surprising result might properly encourage critical examination of the usual assumptions regarding dust populations about stars – e.g., that they are replenished by comets in eccentric orbits or that they are remnants of planet formation.

Proposed Follow-up to IAU Resolution B5 (2006) "Definition of a Planet in the Solar System"

Prof. Jean-Luc Margot[1], Prof. Brett Gladman[2]

[1]University of California, Los Angeles. [2]University of British Columbia

Abstract

The current IAU definition of "planet" is problematic both because it is not quantitative and because it excludes exoplanets. We submitted a proposed resolution (https://bit.ly/IAUproposal) to IAU Commission F2 (Dec. 22, 2023 and Feb. 13, 2024) and IAU Division F (Jan. 17, 2024 and Feb. 13, 2024) with the goal of clarifying the definition and extending it to exoplanets. A proposed improvement is to replace "is in orbit around the Sun" with "orbits one or more stars, brown dwarfs, or stellar remnants". Another proposed improvement is to replace "has cleared the neighbourhood around its orbit" – an impossible standard to meet – with "has sufficient mass to dynamically dominate the neighborhood around its orbit", which can be quantified with measurements of stellar mass, planet mass, and orbital period. This change replaces the “cleared” requirement, which is difficult to evaluate without a complete inventory of a planetary system down to very small sizes, with the ability to dynamically dominate, which can be evaluated with easily measurable properties of the star-planet system.

IAU Resolution B5 is problematic and the problems will not go away on their own. A reasonable approach to astronomical nomenclature is to use physical principles to establish a meaningful threshold, and then adhere to this threshold for definitional purposes. We argue that physically motivated thresholds, even if imperfect, are superior to definitional voids or ambiguities. We encourage community feedback to improve the draft proposal.

From giant planet to brown dwarf: evidence for deuterium burning in old age?

Dr Jan Subjak

Center for Astrophysics | Harvard & Smithsonian. Astronomical Institute, Czech Academy of Sciences

Abstract

The question of distinguishing between planets and brown dwarfs has been the subject of extensive debate in academic circles. While using the deuterium reactions that occur within brown dwarf interiors to differentiate between these groups is a straightforward approach, it may not be the most fundamental method. In some cases, this approach can even lead to intriguing consequences, such as the transition of objects between these groups during late evolutionary stages. The discovery of BD-14 3065b (TOI-4987b) is an example of such a case. This object has a mass that is near the deuterium burning boundary and an extremely inflated radius. The investigation of potential processes that could be responsible for the inflated radius suggests that deuterium burning is a plausible explanation resulting from the heating of BD-14 3065b's interior due to irradiation from its evolving host star.

High Precision Astrometry: Not just for exoplanets!

Mr Conaire Deagan

University of New South Wales

Abstract

One of the goals of the exoplanet community is to find and characterise Earth twins. One upcoming mission - the TOLIMAN space telescope - is designed with innovative optics to achieve high-precision astrometry to detect the presence of an Earth-twin around either Alpha Cen A or B. This level of precision - better than 1 micro arcsecond - has opened new opportunities in stellar physics. By detecting magnetic surface features, such as starspots, we can infer properties of the host stars. These properties include relative inclination between the stars equator and the orbital plane of any planets, the magnitude and frequency of starspots, differential rotation curves, and potentially the presence (or absence) of a Sun-like dynamo. From simulations of the expected performance of TOLIMAN, if it hosts a Sun-like dynamo we expect to be able to measure the inclination of Alpha Cen A to better than 5 degrees. These insights will provide information regarding the stellar environment and habitability of any exoplanets present. Understanding the host star in detail is crucial, as things such as the stellar wind, the frequency and intensity of stellar flares, and the topology of the stellar magnetosphere directly impact the sustainability of biospheres in the surrounding environment.

From Bacteria to Exoplanets: a pioneering approach to biosignature detection

Valeska Molina[1,2], Professor Jeremy Tregloan-Reed[1], Professor Pablo Aguilar[2], Professor Cristina Dorador[2]

[1]Universidad de Atacama. [2]Universidad de Antofagasta

Abstract

Exoplanetary atmospheric characterization plays a pivotal role in unraveling planetary formation, evolution, and potential habitability. Carbon monoxide (CO), wielding a dual role in both biology and astronomy, stands out as a potential biosignature due to its distinct spectral features. Microbial communities thriving in extreme environments, like the Chilean salt flats, serve as valuable analogues for early Earth and potentially for exoplanets. These communities harbor anoxygenic phototrophic bacteria, such as Roseovarius, capable of oxidizing CO.

This study bridges the gap between terrestrial microbial signatures and exoplanetary atmospheres by investigating CO-dependent enzymes (CO-CODH) within Roseovarius sp. isolated from the Atacama Desert's Salar de Llamara. We employed Raman and infrared spectroscopy to identify unique vibrational modes associated with various cellular components. The obtained spectra revealed distinct signatures: Molybdenum active site, FAD (770-776 nm, 1300-1400 cm^{-1}), Fe/S clusters (715-718 nm, 300-350 cm^{-1}), and CO presence (814 nm, 2000 cm^{-1}). These findings support the feasibility of detecting CO-CODH in the atmospheres of Earth-like and super-Earth exoplanets, potentially around ultracool dwarf stars (M7 and later), where the search for habitable transiting exoplanets hold promise. Additionally, atmospheric models were generated to simulate Earth-like planets, enabling a comparative analysis with the acquired spectra. This pioneering approach establishes a crucial link between the microbial ecology of extreme environments and potential biosignatures in exoplanetary atmospheres, advancing our understanding of habitability beyond Earth.

Non-linear stability analysis for perturbed non-collinear equilibrium point in non-resonance case

Dr. Ram Kishor[1], Prof. Badam Singh Kushvah[2]

[1]Central University of Rajasthan, India. [2]IIT(ISM) Dhanbad, India

Abstract

Normalization of Hamiltonian for the non-linear stability analysis of a dynamical system is a key task to study the dynamics in the vicinity of an invariant objects. In the present study, normalization of the Hamiltonian and analysis of non-linear stability in non-resonance case for the Chermnykh-like problem with power-law density profile under the influence of perturbations is performed. Initially, quadratic part of the Hamiltonian is normalized near the non-collinear equilibrium point and then fourth order normalized Hamiltonian is obtained with the help of Lie transforms. In non-resonance case, non-linear stability test is performed using the Arnold–Moser theorem, followed by effects assumed perturbation such as radiation pressure, oblateness and the presence of the disc are analyzed separately and it is observed that in the absence as well as presence of perturbing parameters, non-collinear equilibrium point is unstable in the non-linear sense within the stability range due to failure of the Arnold–Moser theorem.

Detection of sulphur cycle in Enceladus using latest technology advancements

Mrs Aruna Devi TM

International Space University

Abstract

1. Enceladus is the next target in search of life which has almost all the potential biomarkers. Sulphur is one of the most important biosignature found. This sulphur is obtained by various sources. To find the source of sulphur we use latest technological advancement using Artificial intelligence. Using this knowledge we try to find the source of sulphur. By knowing the source whether it is obtained from biotic we could conclude that what organisms to look for in the environment.This further helps us to make our search easier.

Korea's Pre-Earth Encounter Fly-by Mission to Apophis

Young-Jun Choi, Youngmin JeongAhn, Hong-Kyu Moon, Myung-Jin Kim, Dukhang Lee, Bongkon Moon, Minsup Jeong, Chae Kyung Sim, Hee-Jae Lee

Korea Astronomy and Space Science Institute

Abstract

The Korea Astronomy and Space Science Institute (KASI) is preparing a fly-by mission to observe asteroid 99942 Apophis with a multi-wavelength optical camera before its close approach to Earth in 2029. This mission, uniquely timed, will fill a crucial observational gap by providing pre-encounter imagery for comparative analysis with post-encounter data collected by the forthcoming OSIRIS-APEX mission. Our scientific goal is to detect surface changes on Apophis through color variations, which may arise from movements of regolith due to the influence of Earth's tidal torque. This endeavor will not only enable us to observe pre- and post-encounter changes but also enhance our understanding of the surface changes and dynamics of near-Earth objects (NEOs), thereby contributing to planetary defense strategies. International collaboration is crucial for this mission, and we anticipate providing more detailed progress updates during our presentation.

Observation, Behavior and Origin Tracing of Fireballs by PMO-SU Fireball Network

Zhijian Xu[1], Ye Li[1], Nawaz Mahomed[2], Bin Li[1], Shiyong Liao[1], Tinglei Zhu[1], Chen Zhang[1], Haibin Zhao[1]

[1]Key Laboratory of Planetary Sciences, Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing 210023, China. [2]Stellenbosch University, Stellenbosch, South Africa

Abstract

Outer space objects undergo complex physical and chemical processes during entering the Earth's atmosphere, which could deposit energy and cause damage to human life and property. To effectively monitor such events, the establishment of an expansive monitoring network is imperative. A prototype fireball observation network has been established in eastern China, utilizing a combination of cameras and fisheye lens for video recording at each station. Based on the prototype network, five more stations are being built in South Africa and China, respectively. The PMO-SU Fireball Network (Purple Mountain Observatory-Stellenbosch University Fireball Network) aims to span approximately 200,000 square kilometers, anticipated to record over 12,000 meteors per year, primarily targeting those with an absolute magnitude brighter than -2.5. The network is expected to record roughly 140 fireballs annually. Furthermore, each station will be equipped with a spectrum observation camera for obtaining compositional information. By leveraging a fusion of dynamical differential equations and the Markov Chain Monte Carlo (MCMC) method, the network will be capable of calculating the dynamics, trajectories, and orbits of descending objects. The identification of an object's orbital classification will facilitate the distinction between natural and man-made entities and enable the tracing of the origins of natural objects.

Photometric Follow-up for the PLATO Space Mission - an Opportunity for Southern-Hemisphere Observers

Dr. Hans Deeg, Dr. Roi Alonso

Instituto de Astrofísica de Canarias

Abstract

The detection of transiting planets by the PLATO space mission poses a risk of false positives due to contaminating eclipsing binaries. Therefore, a ground-based program is being established for the photometric follow-up of planet candidates. This program will acquire time-series data of planet candidates and adjacent stars during expected transits. This undertaking is part of the broader PLATO Ground-Based Observations Programme, which includes spectroscopy and imaging. The photometric follow-up encompasses work packages for standard and multi-colour follow-up observations, secondary eclipse observations, the definition of analysis tools, the reprocessing of archival photometry, and contributions from amateur astronomers and citizen scientists. Currently, the program's main effort is organizing its observational resources and developing strategies for data collection and reporting, with benchmark observations soon to follow. After PLATO's launch in late 2026, the program's focus will shift to coordinating the observations, analyzing and ensuring their quality, and inserting valid observations into the PLATO follow-up database. The field for the first 2-year-long pointing by PLATO will be a large area, centered at a declination of -48 degrees. Therefore, the photometric follow-up for PLATO provides an excellent opportunity for observers in the Southern Hemisphere to contribute to the PLATO mission, with moderate requirements on observing resources.

Simulation of potentially habitable environments on the surface of exoplanets.

Paola Cunha[1], Luan Ghezzi[1], Douglas Galante[2], Evandro Silva[2], Fabio Rodrigues[2], Ana Carolina Carvalho[2], Junia Schultz[3], Alexandre Rosado[3], Amanda Bendia[2]

[1]Valongo Observatory. [2]University of Sao Paulo. [3]King Abdullah University of Science and Technology

Abstract

M-dwarfs comprise 75% of the stars in the Milky Way and also host a large fraction of the potentially habitable exoplanets. However, the high levels of stellar activity are a challenge in a biological conext. They exhibit frequent and intense flares, exposing their planets to high levels of ultraviolet (UV) radiation. This radiation is crucial for biological systems, but excessive exposure can cause damage to important cell structures. Thus, the aim of this work is to investigate whether life could withstand the environmental conditions of planets orbiting M-dwarfs. For our analysis, we choose, Proxima Centauri b, an exoplanet discovered in 2016 and recently confirmed. It has 1.17 times the mass of Earth and is located in the habitable zone of the system, which is a favorable characteristic for life as we know it. To obtain the results, we performed irradiation experiments with the yeast Rhodotorula collected in Diamantina, MG. The first experiment was performed with a tubular lamp that covers only the UVC region. The second experiment was conducted with a continuous spectrum lamp that covers the entire UV range. The results showed that irradiations using the continuous spectrum lamp are more lethal than the tubular lamp. Additionally, we observed that cells resisted to a fluence of 60000 J/m^2 for the UVC lamp. Assuming an average flux value for the flares on Proxima b (7 W/m^2), this fluence would be reached in about 2.38 hours. Our results provide important data to guide studies searching for biosignatures on exoplanets.

Which stars can form planets: Planetesimal formation at low metallicities

Dr. Geoffrey Andama[1], Dr. Jingyi Mah[2], Dr. Bertram Bitsch[3,2]

[1]Muni University. [2]Max-Planck-Institut für Astronomie. [3]University College Cork

Abstract

The host star and the disc metallicity play a crucial role in the exoplanet diversity. The initial stages of planet formation by core accretion paradigm require the growth of dust material from micrometre size to planetesimal size bodies before core accretion kick-starts. It is still poorly understood how planetesimal formation and, hence, planet formation takes place in low metallicity stellar environments. We explore planetesimal formation in low metallicity stellar environments. We performed global 1D viscous disc simulations, including grain growth, evaporation and condensation of chemical species at the ice lines. We followed planetesimal formation during disc evolution and tested different metallicities, disc sizes and turbulent viscosities. We find that, at solar and sub-solar metallicities, the midplane dust-to-gas ratios increase significantly at the ice lines. However, this leads to planetesimal formation only at the water ice line. In our simulations, [Fe/H] = -0.6 is the lowest metallicity limit for planetesimal formation where a few Earth masses of planetesimals could form. For such extreme disc environments, large discs are more conducive than small discs for planetesimal formation at a given metallicity because pebble flux can be maintained for a longer time, resulting in a longer and more efficient planetesimal formation phase. At lower metallicities, planetesimal formation is less supported in quiescent discs compared to turbulent discs because the pebble flux lasts longer. The amount of planetesimals formed at sub-solar metallicities in our simulations places a limit on core sizes that could only result in the formation of super-Earths.

ExtremeLifeLab: A Toolbox for Field-based Astrobiology Research in Resource-Poor Contexts

Dr Moola Mutondo[1,2], Ms Annette Lombe[1], Ms Salome Mulikita[1]

[1]Copperbelt University. [2]Sunbird Sustainable Solutions

Abstract

Astrobiology is a multidisciplinary field of study that appeals to curious young minds with a fascination for space and its endless possibilities. Astrobiology can also be a gateway science to other fields in astronomy. This paper addresses the astrobiological research theme concerned with the limits of life here on Earth as a stepping stone to understand how life could exist in similar conditions found elsewhere in the solar system and beyond. The ExtremeLifeLab, developed with funding from National Geographic Society, allows the chemical and biological investigation of sites with extreme conditions such extreme pH, temperature, or metal concentration. The presence or absence of keystone extremophiles or keystone extremophilic groups, (especially microalgae for ease of handling) can be verified in situ, using phenotypic characteristics, phylogenetic and functional marker genes (16S, 18S rRNA genes; nifH genes). Reference DNA for 4 Zambian extremophilic sites was made from isolates previously cultured from each site. Data collected by 2 postgraduate researchers and 8 undergraduate students using ExtremLifeLab from two thermophilic sites (Gwisho Hot Springs and Kapisha Hot Springs) will be presented. We show how financially accessible Astrobiology research can be. We hope that many more researchers in resource-poor contexts can exploit local extremophilic sites using ExtremeLifeLab and bring new insights about the limits of life and the interplay between extreme conditions and biology.

The Ophiuchus Disk Survey Employing ALMA (ODISEA): project updates

Lucas Cieza[1,2], Camilo Gonzalez-Ruilova[1,2], Trisha Bhowmik[1,2], Prachi Chavan[1,2], Grace Batalla[1], Dary Ruiz-Rodriguez[3], Anibal Sierra[4]

[1]Universidad Diego Portales (UDP). [2]Millennium Nucleus on Young Exoplanets and their Moons (YEMS). [3]Joint ALMA Observatory (JAO). [4]Universidad de Chile

Abstract

The Ophiuchus Molecular Cloud hosts the largest population of protoplanetary disks within 200 pc and a significant number of embedded young stellar objects (Class I and Flat Spectrum sources), making it an ideal region for the study of disk evolution and planet formation. ODISEA is the largest ALMA survey of nearby molecular clouds and currently involves observations at five different ALMA bands (3, 4, 6, 8, and 10) at resolutions ranging from 50 mas to 1.0". Here we present recent results from ODISEA, including the identification of molecular outflows in young brown dwarfs, a multi-frequency analysis of the ~50 brightest targets, the full size distribution of the ~100 brightest disks in the cloud and the discovery of substructures in several compact disks.

X-rays in the Prime of Life

Dr. Scott Wolk[1], Dr. Bradford Wargelin[1], Dr. Vinay Kashyap[1], Dr. Ignazio Pillitteri[2]

[1]Center for Astrophysics | Harvard & Smithsonian. [2]INAF (Palermo)

Abstract

We discuss the current state of our analysis of the X-ray fluence experienced by 38 planets. Assuming hydrodynamic equilibrium we estimated the mass loss rates of these planets and found 85% of them exceed the mass escape rate of the Earth. At least 3 planets have an estimated mass escape rate of over 1 million times that of the Earth. We specifically examine Two systems, Proxima Cen, Wolf 359, and HD 189733 for which we have over 10 epochs of observations that determine the different environments these planets have experienced over the past 2 decades. In addition, we focus on GJ 273 b TRAPPIST d, e, f, and g all of which have an Earth similarity index of > 0.5. We also examine the impact of individual flares and discuss the implications for like around M stars.

Report from the Division A & F Working Group on Cartographic Coordinates and Rotational Elements

Dr. Brent Archinal[1], Working Group Cartographic Coordinates and Rotational Elements[2]

[1]Astrogeology Science Center, U. S. Geological Survey. [2]International Astronomical Union

Abstract

We report here on the activities of the Working Group (WG) on Cartographic Coordinates and Rotational Elements. Our main work is publishing reports that include recommendations regarding the creation and maintenance of cartographic planetary coordinates.

Our most recent report was published in 2018. After many delays we are beginning to compile the next version of that report. We expect routine updates to recommended orientation and size models resulting from processing or reprocessing of various planetary datasets. These include the models for various bodies, such as Mercury, Venus, Jupiter, Saturn, the Saturnian satellites, Ceres, Comet-67P, Arrokoth, Bennu, and Ryugu.

During 2023–2024, we have largely been considering issues arising after several groups have proposed making a major change in lunar coordinates (https://journees2023.sciencesconf.org/490324). Our presentation will highlight those issues and related WG publications.

Changes to improve the orientation model for Mars are also under consideration.

Our presentation will describe the membership and operation of the WG, numerous types of community requests that we respond to, and our increasing cooperation with other groups.

The WG has concerns that it is becoming over-extended. Input on that and on our recommendations themselves is welcome. In the meantime, the WG has continued to make its efforts and activities known via its website (https://www.usgs.gov/centers/astrogeology-science-center/science/iau-wgccre) and by various publications and presentations. Further information on the WG is given in our activities reports to the IAU, available from the main IAU WG website (https://www.iau.org/science/scientific_bodies/working_groups/100/).

Investigating Links Between Mechanical Properties, Petrography, and Geochemistry of Meteoritic Materials to Comment on the Early Breakup of Meteoritic Materials on Atmospheric Entry

Miss Llelani Coetzer[1], Dr Matthew Mayne[1], Prof Nawaz Mahomed[2]

[1]Department of Earth Sciences, Stellenbosch University. [2]Department of Mechanical and Mechatronic Engineering, Stellenbosch University

Abstract

This project aims to investigate the petrography and geochemistry of meteoritic materials in an effort to explore the relationship between the geological makeup of meteorites and their mechanical properties, shedding light on their behaviours during atmospheric entry, in particular, the early breakup of meteoroids at relatively low compressive stress. The project aligns with the initiative "Research on the Observation, Behaviour, and Origin Tracing of Outer Space Objects Entering the Atmosphere," which includes the investigation of factors contributing to early meteoritic breakup.

Comprehensive analysis of meteoritic materials, ranging from iron meteorites to chondrites, will be undertaken, including thin section petrography, SEM, XRF, LA-ICP-MS, CT scanning, and statistical analyses. Specific focus will, among others, be on the minerals present, their proportions and makeup, the elemental and mineral compositions, and how it may relate to macro- and microstructural features such as porosity within the samples. The expected results can be used, in combination with studies relating to mechanical strength, for the effective quantification of material composition, structural properties, and material behaviour.

The larger integrated research study investigates the influence of shock waves, drag, ablation and fragmentation on meteoritic body mechanical properties, considering factors such as permeability, porosity, and phase transformations during atmospheric entry. This interdisciplinary approach aims to provide valuable insights into the complex behaviours of meteoritic materials, contributing to our understanding of their origins and behaviours in the solar system.

[1]Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, USA. [2]Lowell Observatory, Flagstaff, Arizona, USA. [3]Northern Arizona University, Flagstaff, Arizona, USA. [4]Smead Department of Aerospace Engineering Sciences, University of Colorado Boulder, Boulder, Colorado, USA. [5]Astronomical Institute of the Academy of Sciences of the Czech Republic, Ondřejov, Czech Republic. [6]Johns Hopkins University, Applied Physics Laboratory, Laurel, Maryland, USA

Abstract

The Double Asteroid Redirection Test (DART) mission impacted Dimorphos, the satellite of binary near-Earth asteroid (65803) Didymos, on 2022 September 26 UTC. We estimate the changes in the orbital and physical properties of the system due to the impact using ground-based photometric and radar observations, as well as DART camera observations. We estimate that the DART impact instantaneously changed the along-track velocity of Dimorphos by −2.63 ± 0.06 mm s^{-1}. Initially, after the impact, Dimorphos's orbital period had changed by −32.7 minutes ± 16 s to 11.377±0.004 h. We find that over the subsequent several weeks the orbital period changed by an additional 34 ± 15 s, eventually stabilizing at 11.3674 ± 0.0004 h. The total change in the orbital period was −33.25 minutes ± 1.5 s. The post-impact orbit exhibits an apsidal precession rate of 6.7 ± 0.2 deg day^{-1}. Under our model, this rate is driven by the oblateness parameter of Didymos, J_2, as well as the spherical harmonics coefficients, C_{20} and C_{22}, of Dimorphos's gravity. Under the assumption that Dimorphos is a triaxial ellipsoid with a uniform density, its C_{20} and C_{22} estimates imply axial ratios, a/b and a/c, of about 1.3 and 1.6 respectively. Pre-impact images from DART indicate Dimorphos's shape was close to that of an oblate spheroid, and thus our results indicate that the DART impact significantly altered the shape of Dimorphos.

Searching for globular clusters in the inner halo of the Circinus galaxy

Dr Casmir Obasi[1], Professor Matias Gomez[2], Professor Dante Minniti[2], Professor Maria Alonso[3], Dr Laura Baravalle[3], Dr Bonaventure Okere[1]

[1]Nasrda-Centre for Basic Space Science. [2]Instituto de Astrofísica, Facultad de Ciencias Exactas, Universidad Andres Bello, Santiago Chile. [3]Departamento de Fisica, Universidade Federal de Santa Catarina, Trinidade 88040-900, Florianopolis, Brazil. 5Instituto de Astronomía Teórica y Experimental (IATE, CONICET-UNC), Laprida 854, Córdoba, Argentina.

Abstract

In this study, we search for Globular Clusters (GCs) in the inner halo of the Circinus galaxy using a combination of observational data. Our dataset includes observations from the VISTA Variables in the Vía Láctea Extended Survey (VVVX), optical data from Gaia Release 3 (DR3), and observations from the Dark Energy Camera (DECam). These multiple data sources provide a comprehensive basis for our analysis. Our search was concentrated within a 50 kpc radius from the centre, leading to the identification of 93 sources that met our established criteria. To ensure the reliability of our findings, we conducted multiple examinations for sample contamination. These examinations incorporated tests based on Gaia Astrometric Excess Noise (AEN), the Blue Photometer (BP)/Red Photometer (RP) Excess Factor (BRexcess), as well as comparisons with stellar evolution models. This analysis confidently classified 41 sources as genuine GCs, as they successfully passed both the 3σ Gaia AEN and BRexcess tests. We used the ISHAPE program to determine the structural parameters (half-light radii) of the GC candidates, with a peak effective radius of 4$\pm$ 0.5 pc. The catalogue mainly consists of bright GCs. Relationships between colour, size, and distance were found in the GC candidates, alongside confirmation of bi-modality in colour distributions.

Four new eclipsing accreting ultracompact white dwarf binaries found with the Zwicky Transient Facility

Ms Jasmine Khalil

University of Amsterdam

Abstract

Context. Accreting ultracompact binaries contain a white dwarf that is accreting from a degenerate object and have orbital periods shorter than 65 minutes.

Aims. The aims of this work are to report the discovery and the orbital period of four new eclipsing accreting ultracompact binaries found using the Zwicky Transient Facility, and to discuss their photometric properties.

Methods. We searched through a list of 4171 dwarf novae compiled using the Zwicky Transient Facility and used the Box Least Square method to search for periodic signals in the data.

Results. We found four eclipsing new eclipsing accreting ultracompact binaries with orbital periods between 25.9–56 minutes, one of which is previously published as an AM CVn, while the other three systems are new discoveries. The other two shorter period systems are likely also AM CVn systems, while the longest period system (P=56 minutes) shows multiple super-outbursts observed in a short amount of time which might be more consistent with it being a Helium-CV

Violent dynamics around the Galactic center.

Professor Roberto Capuzzo Dolcetta

Dep. of Physics, Sapiena, University of Roma, Italy

Abstract

The center of our Galaxy hosts a massive compact object, claimed to be a super massive black hole of about 4 million Solar masses. This result is coming mainly bu the accurate determination of the movement of a set of stars (so called S-stars) revolving around the massive object at distances above 1500 times the Schwarzschild radius of the alleged massive black hole. The situation is around the threshold between the region of very strong gravitational field, where relativistic effects should be taken into account thoroughly, and that where an approximated Post newtonian treatment suffices. In this presentation I will describe recent results about the expected precession, gravitational red shift, etc., for stars plunging very close to the Galactic center that would be likely needed to investigate the innermost dynamical physics of our Galaxy. This work has a clear feedback on checking validity of the General Theory of Relativity in strong field regime.

The Radio Emission from Young Massive Stars

Mr. Solomon Appekey, Dr. Stuart Lumsden, Professor Melvin Hoare

University of Leeds

Abstract

Studying young massive stars or young stellar objects (YSOs) at radio wavelengths together with complementary millimetre wavelength data is very important for understanding the complete process of the formation and evolution (especially the mechanism behind the production of jets and outflows) of these objects. In this study, we investigate a sample of 20 YSOs which form the IRAM Northern Extended Millimeter Array (NOEMA) CORE large program sample. These targets are luminous ($L > 104L\odot$), close by ($d < 6$ kpc) and well-studied young massive stars in the northern hemisphere. We have studied 8 of these targets that did not have any previous Karl G. Jansky Very Large Array (JVLA) data prior to this work. This study was performed in JVLA's A-configuration at 6 GHz and at a resolution of 0.33 arcseconds. For our targets, we detected radio continuum emission from 7 of these objects including the detection of 2 jets. Additionally, we found evidence of variability among 2 of our targets. For the entire sample, we performed a comprehensive radio and millimetre study where we found and associated observed millimetre cores with radio detections (including jets, jet lobes and HII regions) using results from this work and literature. One of the goals of this study is to investigate the orientation of jets to their respective millimetre emission and or discs (if present). We found evidence of a perpendicular orientation of the detected jet to the millimetre emission for the target NGC 7538S. Also, 2 of our targets show a perpendicular disc-jet orientation (using information from literature). Our sample also show divergence from low-mass stars and HII regions in radio luminosity and bolometric luminosity parameter space which indicates that young massive stars are likely to be formed through a scaled up version of their low-mass counterparts. We also find a strong correlation between sample and core masses which may suggest that larger global or sample masses tend to lead to larger core masses.

The death of stars in binary systems as seen by SPHERE/VLT

PhD Aymard BADOLO[1,2], Eric LAGADEC[2], Sié Zacharie KAM[1], Mamadou N'DIAYE[2], Jean KOULIDIATI[1]

[1]Université Joseph KI-ZERBO. [2]Observatoire de la Cote d'Azur

Abstract

During the late stages of their evolution, low- and intermediate-mass stars reach the asymptotic giant branch (AGB), where they expel their gas, enriched with newly transformed elements, into the interstellar medium (ISM). This mass-loss process is the main driver of the late evolution of these stars and one of the main sources of ISM enrichment, but it's not yet understoud well. For decades, the description of the mass loss of these stars has assumed that AGB stars are unique. A growing body of work clearly shows that this is not the case, such as the recent paper by Decin et al. (2020) in Science, which shows that binaries shape the gas flows of most AGB stars. Studying the distribution of dust near the surface of these stars is therefore key to understanding how binaries can affect their mass loss. We performed a polarimetric survey of the dust around a sample of 53 nearby AGB and RGB stars, mainly symbiotic stars, using the SPHERE (specially ZIMPOL) extreme adaptive optics instrument installed on the VLT in Chile. This allowed us to map the dust distribution around the AGB stars with an angular resolution of 20 milliarcsec. We thus made circumstellar envelop models using RADMC-3D in order to determine ceratains parameters of theses stars and to better understand the phenomenon of their loss of mass , with a particular focus on binarity.

Key words: s*tars: mass loss – stars: symbiotic, binarity – stars: polarimetry*

A Study of the Mechanism for X-ray Emission from Symbiotic Stars

Prof Romanus Nwachukwu Eze

University of Nigeria, Nsukka, Enugu State, Nigeria

Abstract

We propose to address the mystery surrounding the genesis of X-ray emission from Symbiotic Stars (SySts), a broad class composed of interacting binary systems formed from the combination of a red giant or supergiant that transfers mass to a much hotter primary, either a white dwarf (WD) or neutron star. A century ago, it was identified the first such system in the odd variable star, R Aqr, appeared to have an optical spectrum typical of an M dwarf but with bright [O III] lines, a much higher ionization state than expected from a cool star. Decades later SySts were detected in X-rays, but this has not simplified the situation. Researchers have differing perspectives on the genesis of X-ray emission, resulting in four major classifications of X-ray emitting SySts with potentially four separate origins or perhaps simply different variants of the same mechanism. However, in many cases, the exact processes and physics responsible for X-ray emission remain unknown, in part because their distances are either poorly determined or simply unavailable. To estimate the genuine X-ray luminosities and spectra of SySts, We will combine newly available data on distances to X-rays-emitting SySts from ESA's GAIA mission with archival X-ray data from the Chandra, XMM-Newton, and Swift satellites. This can be done with improved and expanded catalogs of SySts and the new all-sky eRosita survey data. Comparing this significantly enhanced data set to the various postulated categories will enable a better grasp of the physics and origins of these strange systems.

Strange stars and their formation mechanism

Dr Mohamad alassiry

Syrian Astronomical Association

Abstract

the energy based on the quantum chromodynamic theory is less than the energy needed to obtain a nucleus Neutron stars, but we need a mass between 2 to 2.5 of the mass of the sun M⊙and with a radius of less than 10 km, from which we can conclude that the heavier neutron stars may turn into strange stars after the supernova stage, where the supernova either forms a neutron star or turns into a quark nova forming a strange star.And the quarks can become free if the temperature is very high in addition to that the baryonic density is sufficient, but so far the necessary confirmation for this has not been obtained, especially the transition from the state of the hadron gas to the state of the quark-gallon plasma, which is the expression the athlete reports on the conditions for forming a strange star.But in the laboratory,we can get the strange quark by switching between the upper and lower quarks that form hadrons,and it is also possible to obtain even with a small probability of electrons.Although the strange stars are not new,the technological and scientific development recently has brought this topic back to the fore,especially the follow-up techniques are developing, because what is required is to follow some neutron stars and observe the signals coming from them that prove or deny their transformation into strange stars, and some technologies have come to believe that and the difference between neutron stars can be monitored.And strange.

High Resolution Spectra of the Galactic Binary Pulsar 4U 1907+09

Dr. Jun Yang[1], Dr. Norbert Schulz[2], Jose Torrejon[3], Dr. Paul Hemphill[2], Prof. Claude Canizares[2]

[1]Center for Astrophysics | Harvard & Smithsonian. [2]Massachusetts Institute of Technology. [3]Universidad de Alicante

Abstract

The accreting pulsar 4U1907-09 is one of ~35 high-mass X-ray binaries with known high magnetic field strengths. A detected cyclotron resonance scattering feature (CRSF) at ~19 keV leads to a field strength of around 2E12 G. The system consists of a slowly-rotating (~440 s) X-ray pulsar accreting from the stellar wind of an O8/9 supergiant. The X-ray pulsar is in a close (~8.37 d) elliptical orbit (e ~ 0.28) around its donor.

We conducted an analysis of four High Energy Transmission Grating observations with the Chandra X-ray Observatory for a total of ~140 ks and one NuSTAR observation for 78 ks, at different orbital phases, to probe the variation of the absorbing column around the orbit.

We measure line fluorescence at Fe K and possibly Si K and other lower Z elements to study dense clumps in the wind of the pulsar's companion star. The details of the NuSTAR observation are used to determine the higher energy continuum beyond 10 keV.

Extracting the Physical Parameters of Platais 8 Open Cluster with GAIADR3

Elnaz Bakhshi

Institute for Advanced Studies in Basic Sciences (IASBS)

Abstract

Using G, Bp, Rp photometry band and proper motion astrometry data from GAIA's latest version of DR3, we have successfully identified potential cluster members of the nearby open cluster Platais 8. These members were pinpointed within a 5-degree radius from the cluster's center, considering a distance modulus of (m − M)0 = 5.88 mag (which corresponds to approximately 150 pc). By establishing a new cluster center at α = 08h 55m 36s, δ = -58° 09' 30", we have gained valuable insights into the structure of Platais 8. Our calculations also reveal a total cluster mass of approximately 230 M⊙, as well as the 2D half-number and half-mass radii. Furthermore, we have determined the surface density of members within a 6-degree field and explored the dynamics of mass segregation within the cluster. Additionally, we have analyzed the mass function of cluster members using a power-law ξ(m) ∼ m-α, uncovering distinct slopes for high and low mas stars. Notably, our examination of the color-magnitude diagram of Platais 8 has led to the identification of a significant population of binary and triple systems, performing a series of Monte Carlo simulations, we obtained a binary fraction stars. Indicating that this open cluster contains a large population of unresolved binaries. Finally, we corrected the MF slopes for the effect of unresolved binaries and found low- and high-mass slopes.

EXPLORING THE JET FORMATION IN BINARY SYSTEMS APPLYING 3D MHD SIMULATIONS

Mr. Mostafa Sepahvand

Institute for Advanced Studies in Basic Sciences, Zanjan, Iran

Abstract

We conducted axisymmetric MHD simulations to investigate the formation of an ideal magnetized jet that originates from a disk acting as a boundary. Our simulations showed that the magnetized jet consistently launched and reached a stable state. To further our research, we extended the model setup to three dimensions and conducted 3D MHD simulations of the jet launched from a disk surface, achieving a stable and appropriate model setup. Furthermore, we expanded our study by including the companion star and examining the influence of the Roche potential on the jet material. Specifically, we investigated whether the inclusion of the companion star in the model significantly affects the dynamical evolution of the jet. Our findings indicate that the host accretion disk is responsible for the primary physical effects and characteristics of the outflow on a larger scale, whereas the direct tidal effects on the jet dynamics have a substantial impact, particularly in the vicinity of the Roche lobe and towards the secondary star.

[3]Dark Sky Observatory, Appalachian State University, Department of Physics and Astronomy. [4]Department of Physics, Florida International University

Abstract

Short period solar-type binaries are strongly magnetic. As stellar winds leave the poles, this results in a loss of angular momentum, ultimately, decreasing the orbital periods. Extreme mass ratio binaries (EMRB's, $m_2/m_1 \lessapprox 0.2$) result from this process. Recently, our research group has observed the following EMRB's:

GSC06462-00195 is an ~F4V eclipsing binary with a period of 0.63348292d. The system has a mass ratio of q = 0.0937. Its fill-out is a high 66% with an inclination of ~82.5° with an eclipse duration ~109.5 minutes.

NSVS6429576 has a period of 0.5366686 d and a spectral type of ~F2.5. Despite

its low amplitude, DV=0.284 mags, the light curve shows a long total eclipse duration of 96.6 minutes. Its Roche lobe fill-out is found to be 40% along with a mass ratio of only 0.11 and its period appears to be decreasing. The inclination is 83.9˚. The third light was determined.

GDS_J1139444-611732 is a Southern solar type (T ~ 6250K), marginally overcontact, eclipsing binary. The amplitude of the light curves was 0.56 mags in V. A Wilson-Devinney Program solution gives a m_2/m_1=0.1790, a large component temperature difference of 780 K and a fill-out of only 4%. An eclipse duration of $\gtrsim$39 minutes was found.

TYC 2402 0643 1 was found to have a mass ratio q=0.207. Its Roche lobe fill-out is ~22%. It has a period of 0.39958073d. The inclination is high, 83.4±0.1˚ resulting in a total eclipse duration of 43 minutes. The temperature of the primary component ~5250K.

[1]Universität Duisburg-Essen. [2]University of Leicester. [3]University of Vienna. [4]University of Potsdam. [5]National Institute for Astrophysics (INAF). [6]Thüringer Landessternwarte Tautenburg

Abstract

Recent observations of high-mass young stellar objects (HMYSOs) with masses $M_*\geq 10\ M_\odot$ uncovered outbursts with accretion rates exceeding $\sim 10^{-3}\ M_\odot\ yr^{-1}$. We utilise 1D time-dependent models of protoplanetary discs around HMYSOs to study burst properties. We find that discs around HMYSOs are much hotter than those around their low-mass cousins. As a result, a much more extended region of the disc is prone to the thermal hydrogen ionisation and magnetorotational (MRI) activation instabilities. The outbursts triggered by these instabilities, however, always have too low accretion rates and are one to several orders of magnitude too long compared to those observed from HMYSOs to date. On the other hand, bursts generated by tidal disruptions of gaseous giant planets formed by the gravitational instability of the protoplanetary discs yield properties commensurate with observations, provided that the clumps are in the post-collapse configuration with planet radius $R_p\geq 10$ Jupiter radii.

Pulsar glitch activities estimations: the spin parameters approach

Dr Innocent Eya

University of Nigeria, Nsukka

Abstract

Glitch activity refers to the change in pulsar spin frequency per year due to rotational glitches. It is an important tool for studying the dynamics of super-nuclear matter using neutron star interiors as models. Glitch events are usually observed in the spin frequency and frequency derivative of pulsars. As a pulsar ages, the rate of occurrence of these glitches decreases. The activity parameter can be calculated by performing linear regression on the cumulative glitches of a given pulsar over a given period. However, this method is only practical for pulsars with multiple regular glitch events. Unfortunately, there are only a few pulsars with such records due to the scarcity of glitch events and the difficulty of monitoring all known pulsars. This makes it difficult to study neutron star interiors with multiple pulsars using the activity parameter. This analysis investigates the relationship between the glitch activity parameters and pulsar spin parameters (spin frequency, frequency derivatives and characteristic ages). We found that a quadratic function provides a better description of the relationship between the activity parameters and pulsar spin parameters than the commonly used linear functions. Using this information, we were able to estimate the activity parameters of other pulsars that do not have records of glitches. We observed that the relationship between the estimated activity parameters and pulsar spin parameters in the ensemble of pulsars is consistent with that of the observed.

Radio emission from Massive Protostars in the SARAO MeerKAT Galactic Plane Survey

Dr Willice Obonyo[1,2], Prof. Melvin Hoare[3], Prof. Stuart Lumsden[4]

[1]Technical University of Kenya. [2]University of South Africa. [3]University Leeds. [4]University of Leeds

Abstract

L-band radio emission from known massive young stellar objects (MYSOs) in the SARAO MeerKAT Galactic Plane Survey were studied to search for non-thermal radio emitters from the sample. A total of 398 massive protostars, identified from the RMS survey, lie within the region covered by the survey. One hundred and sixty four fields that host the protostars are isolated from nearby bright HII regions, and can be studied to establish the nature of the emission from any ionized jets in the fields. Seventy four of the fields have jets with five-sigma detections and above, corresponding to a detection rate of 45%. The MeerKAT fluxes of the detections and the upper limits of the non-detections, together with any other fluxes from previous observations, were used to estimate the spectral indices of the jets to search for the presence of non-thermal radiation. If a source manifests a single emission at a given observation but is resolved into multiple components in observations of higher resolutions, then the sum of the fluxes of the components were used in estimating the indices. The spectral energy distribution of some of the sources as well as as their radio-luminosities display evidence of non-thermal emission, especially from extended sources.

Multiwavelength Study of Be/X-ray Binary Stars

Mr Thuto Ndlovu

University of KwaZulu-Natal (UKZN)

Abstract

Be/X-ray binary stars are the largest subclass of high-mass X-ray binaries which comprise a neutron star in an eccentric orbit around a massive B spectral type star. They undergo X-ray outbursts which come in two flavours: Type I and Type II. The origin of the outbursts is due to the complex interaction between the neutron star and circumstellar disc around the Be star. We perform a systematic study of circumstellar discs of Be/X-ray binaries to demonstrate observational signatures of the Kozai-Lidov mechanism. The results show that circumstellar discs undergo morphological variability which influences the mass accretion onto the neutron star.

Fine Structure of the Hα Age-Chromospheric Activity Relation in Solar-Type Stars

Paulo Vitor Souza dos Santos[1], Gustavo Porto de Mello[1], Diego Lorenzo-Oliveira[2], Erica Bhering[1], Felipe Almeida-Fernandes[3], Ignasi Ribas[4,5]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil. [2]Laboratório Nacional de Astrofísica, Itajubá, Brazil. [3]Universidade de São Paulo, São Paulo, Brazil. [4]Institut de Ciències de l'Espai, Barcelona, Spain. [5]Institut d'Estudis Espacials de Catalunya, Barcelona, Spain

Abstract

Excess chromospheric emissions within deep photospheric lines are useful proxies of stellar magnetism for FGK stars. This emission decays with stellar age and is a potential determinant of this important stellar quantity. We report Hα chromospheric fluxes for 511 solar-type stars in a wide range of masses, [Fe/H], ages and stages of evolution, from high S/N, moderately high-resolution spectra and calibrated absolutely with model atmospheres. The comparison of Hα and H+K (Ca II) chromospheric fluxes reveals a strong metallicity bias affecting H+K fluxes thereby metal-rich stars with deep line profiles mimic low levels of chromospheric flux, the converse being true for metal-poor stars. This bias blurs the age-activity relation, precluding age determinations for old, inactive stars unless the relation is carefully calibrated with mass and [Fe/H] terms. Hα chromospheric losses do not suffer from significant metallicity biases and are competitive age indicators up to ages 6 Gyr. The Hα age-activity-mass-metallicity calibration fully satisfies the theoretical expectation that (other parameters being equal) more massive stars possess narrower convective zones and are less active than less massive stars, while more metal-rich stars have deeper convective zones and appear more active than metal-poorer stars.

PRECISION ANALYSES OF THREE SOLAR TYPE BINARIES, AND THEIR THIRD COMPONENTS: V471, V1115 CASSIOPEIAE, AND V642 VIRGINIS

Dr. Ronald Samec[1], Dr. Walter Van Hamme[2], Dr. Marek Wolf[3]

[1]Faculty Research Associate, Pisgah Astronomical Research Institute Long researcher, Dark Sky Observatory, Appalachian State University, Department of Physics and Astronomy. [2]Florida International University, Miami, USA. [3]Astronomical Institute, Charles University, Czech Republic.

Abstract

Recently, BVR_cI_c light curve observations were taken of A type W UMa contact systems V471 and V1115 Cassiopeiae and the detached binary, V642 Virginis. They have undergone Wilson-Devinney (W-D) analyses. V1115 Cas is a totally eclipsing binary with a mean V magnitude of 14.32, an amplitude of DV=0.532 mags and a period of 0.32328d. V471 Cas has a period of 0.40101d and a magnitude range of 13.6-14.4. Both studies include extensive period studies with many new eclipse timings and a determination of the minimum masses of the third bodies. In an 82-year period study of V471 Cas, an analysis by Wolf, a sinusoidal oscillation results which yields a composite third body of mass 0.10 $M_\odot$. An analysis of the light curve reveals that the system has a mass ratio of q~0.89 (M_2/M_1). From our 19-year period study of V1115 Cas, the residuals form a sinusoidal curve. An analysis of this curve yields a third body of minimum mass, 0.50 $M_\odot$. The system has a somewhat extreme q=0.23. The inclination is high, 86.06° resulting in a total eclipse. V642 Vir is a polar spotted, well detached, UV Leo-type, low mass, ~K6V system. The O-C plots show a low amplitude oscillation of residuals which points an orbiting third body, a dwarf of minimum mass, 0.15 $M_\odot$ in an eccentric orbit (e=0.41), with an orbital period of 20 years. The odd light curves of V642 Virginis indicate that it has polar spots.

Astrophysical Jets in Binary Systems; 2D

Mrs Leyla Karimi Akbarabadi

Institute for Advanced Studies in Basic Sciences (IASBS)

Abstract

Our research investigates the formation and launch of magnetized jets from the inner regions of young stellar objects (YSOs), specifically protostellar disks. To achieve this, we used the PLUTO code to implement time-dependent magnetohydrodynamic equations. Our simulations were 2D and considered the accretion disk as a boundary. We varied physical parameters such as magnetic field intensity, mass injection ratio, and potential wells generated by a single central star or a binary system with different masses. We also added the gravitational potential of the companion star in the binary system to observe the direct effects of tidal forces on the jet structure. Our observations revealed that stronger magnetic fields result in faster but less dense jets. Additionally, mass injection leads to massive jets that further slow down the jet's speed. We also found that tidal forces have a significant impact on the jet structure, especially in areas close to the disk and the launching region. The effect of tidal forces directly on the jet structure is undeniable, with the most significant impact being on the transfer of tidal forces from the disk to the jet.

RECENTLY OBSERVED MARGINALLY OVERCONTACT SOLAR TYPE BINARIES: TX CMI, DW CMI, SZ SCL, V590 CAM, and GDS_J1139444-61173

Dr. Ronald Samec[1], Dr, Daniel Caton[2]

[1]Faculty Research Associate, Pisgah Astronomical Research Institute Long researcher, Dark Sky Observatory, Appalachian State University, Department of Physics and Astronomy. [2]Appalachian State University, Department of Physics and Astronomy

Abstract

Marginally contact solar-type binaries occur when binary stars have recently come into contact or are undergoing Thermal Relaxation Oscillations. These systems have not come into thermal contact. Five recently observed systems are in this configuration.

GDS_J1139444-611732 is a solar-type (T ~ 6250K), overcontact, eclipsing binary. A Wilson-Devinney Program (WD) solution gives a m_2/m_1=0.1790, a large component temperature difference of 780 K is due to recent contact and a fill-out of only 4%. An eclipse duration of 39 minutes was found.

TX CMi: Fifty-five total times of minimum light are included in the 61-year period study (p=0.38d). From these we determined that the period is increasing. A W-D analysis reveals that the system is a W UMa binary with a mass ratio near unity. q~1.00. Its Roche Lobe fill-out is ~10%. One spot was needed in the modeling. The temperature difference of the components is only ~90 K, so the stars are nearly twins, with the secondary component as the slightly cooler one. The inclination is high, 86.9º.

DX CMi: Thirty-five total times of minimum light are included in this W-type W UMa's 19.3 year period study. The period is weakly decreasing with a quadratic term of $-1.9X10^{-11}$. A W-D analysis reveals that this W-type W UMa binary has a mass ratio near unity, q~1.1. Its Roche Lobe fill-out is ~10%. One weak spot was needed. The temperature difference of the components is ~260 K.

SZ Scl and V590 Cam (Roche Lobe fill-out is 7% and ~4%, respectfully) were also observed.

Light Curve Analysis of Contact Binary Stars Using BSN Software

Atila Poro[1,2], Ehsan Paki[3]

[1]Astronomy Department of the Raderon AI Lab., BC., Burnaby, Canada. [2]Binary Systems of South and North (BSN) Project - https://bsnp.info/. [3]Binary Systems of South and North (BSN) Project

Abstract

Light curve analysis of binary systems using existing programs and the Markov chain Monte Carlo (MCMC) method or Monte Carlo (MC) simulation is generally a time-consuming process. There were some suggestions for this issue, but they were challenging to implement by users. We introduce the BSN software, whose name is taken from the Binary Systems of South and North (BSN) project. This software is the PHysics Of Eclipsing BinariEs (PHOEBE) and the Wilson-Devinney (WD) codes based, and usable for the analysis of light curves of contact binary systems, which has the fastest MCMC speed compared to other existing programs. The BSN software offers more features and is easier to use for analyzing the light curve on ground- or space-based data, taking into consideration scientific principles. This software follows all the standard scientific requirements, the same as other programs, for light curve analysis of contact systems. We also used machine learning in this software to suggest the location of the star spot (if needed) to the user. The BSN software can estimate and display absolute parameters along with stellar evolution diagrams in different methods. Calculations and display of orbital period changes (O-C) of binary systems is one of the other parts of this software, which can be drawn using linear, parabolic and sinusoidal MCMC fits. Currently, the contact binaries section of this software is finished and can be presented.

[4]Observatorio Astronómico Nacional, Universidad Nacional Autónoma de México, Apartado Postal 877, Ensenada C.P. 22800, B.C., México

Abstract

Multiband photometric investigations for eight binary systems of the W Ursae Majoris (W UMa)-type are presented. Six systems are presented for the first time to analyze their light curves. All the analyzed systems have a temperature below 5000 K and an orbital period of less than 0.28 days. We extracted primary and secondary minima from the ground-based observations of these systems. According to a few observations reported in the literature, linear fits were considered in the O-C diagrams, and new ephemerides were presented. Light curve solutions were performed using the PHysics Of Eclipsing BinariEs (PHOEBE) code. The results of the mass ratio and fillout factor indicate that the systems are contact binary stars. Six of them showed the O'Connell effect, and a cold starspot on each companion was required for light curve solutions. Their absolute parameters were estimated and evaluated by two other methods. In this study, the empirical relationship between the orbital period and semi-major axis was updated using a sample consisting of 414 contact binary systems and the Monte Carlo Markov Chain (MCMC) approach. Also, using Machine Learning (ML) and the Artificial Neural Network (ANN) model, the relationship between P-T1-M1 was updated for a better estimation of the mass of the primary star.

2D Parameter Relationships for W UMa-type Systems Revisited

Atila Poro[1,2], Ehsan Paki[2], Ailar Alizadehsabegh[3]

[1]Astronomy Department of the Raderon AI Lab., BC., Burnaby, Canada. [2]Binary Systems of South and North (BSN) Project - https://bsnp.info/. [3]Tabriz University, Tabriz, Iran

Abstract

Reviewing the empirical and theoretical parameter relationships between various parameters is a good way to understand more about contact binary systems. In this investigation, two-dimensional (2D) relationships for P-M_V(system), P-L1,2, M1,2-L1,2, and q-L_ratio were revisited. The sample used is related to 118 contact binary systems with an orbital period shorter than 0.6 days whose absolute parameters were estimated based on the Gaia Data Release 3 (DR3) parallax. We reviewed previous studies on 2D relationships and updated six parameter relationships. Therefore, Markov chain Monte Carlo (MCMC) and machine learning methods were used, and the outcomes were compared. We selected 22 contact binary systems from eight previous studies for comparison, which had light curve solutions using spectroscopic data. The results show that the systems are in good agreement with the results of this study.

Estimating the Absolute Parameters of W UMa-type Binary Stars Using Gaia DR3 Parallax: Limitations

Atila Poro

Astronomy Department of the Raderon AI Lab., BC., Burnaby, Canada. Binary Systems of South and North (BSN) Project - https://bsnp.info/

Abstract

W UMa-type systems are significant astrophysical tools for studying the formation, evolution, and structure of stars. It is possible to get insight into the evolution of stars by studying contact binary systems, including relationships between parameters and important stellar elements like mass, luminosity, and surface gravity. Deepest investigations are required to solve the numerous unanswered concerns and unsolved challenges regarding these systems in our current understanding. To obtain reliable results and overcome some challenges, it is necessary to measure accurately and use appropriate methods for computations and analysis. One of the issues is estimating absolute parameters after observation and data reduction processes, analysis of orbital period variations, and light curve solution. When just photometric data is available, there are several methods based on various parameter relationship equations that were presented through investigations. The use of Gaia DR3 parallax is one method that has been utilized recently to estimate the absolute parameters of contact binary systems we attempted to investigate different aspects of using this method to estimate absolute parameters.

Period-Luminosity Relationship for Delta Scuti Stars Revisited

Ailar Alizadehsabegh[1], Atila Poro[2], Javad Jafarzadeh[3]

[1]Tabriz University, Tabriz, Iran. [2]The Raderon AI Laboratory, Astronomy Department, Burnaby, BC, Canada. [3]Department of Physics, University of Texas at Dallas, 800 W. Campbell Rd., Richardson, TX 75080, USA

Abstract

The Gaia DR3 parallax approach was used to estimate the absolute parameters of 2375 Delta Scuti stars from the ASAS catalog. The selected stars have a variety of observational characteristics, with a higher than 80% probability of being Delta Scuti stars. We have displayed all the stars in the Hertzsprung-Russell (H-R) diagram along with the Delta Scuti instability strip, the Zero Age Main Sequence (ZAMS), and the Terminal-Age Main Sequence (TAMS). Then, we determined which fundamental and overtone modes each star belongs to using pulsation constant (Q) calculations. In addition, we evaluated the parameters in the Q calculation equation using three machine learning methods, which showed that surface gravity and temperature have the greatest effect on its calculation. The Period-Luminosity (P-L) relationship of the Delta Scuti stars was also revisited. Eventually, using least squares linear regression, we made four linear fits for fundamental and overtone modes and updated their relationships.

Making a HASH* of it: Strange Galactic alignments and solving the sulphur anomaly in Planetary Nebulae*HASH: The Hong Kong, AAO, Strasbourg H-alpha Planetary Nebulae database and reseaerch platform

Prof Quentin Parker

The University of Hong Kong

Abstract

Planetary Nebulae (PNe) are a relatively rare but powerful late-stage stellar population in terms of what we can learn about stellar evolution and the chemical enrichment process of entire Galaxies. Their ionised shells exhibit numerous and strong emission lines over a wide range of the electromagnetic spectrum. As such they represent highly useful “laboratories” for studying the plasma physics of these celestial objects. Because most radiation from PNe is emitted via their strong emission lines they can be found to enormous distances outside of our own Galaxy. Their rich variety of lines also enables estimation of elemental abundances, expansion velocity of the nebula and associated kinematic age. HASH (Hong Kong/AAO/Strasbourg H-alpha PN catalogue) is a PNe mutliwavelength database of all currently known Galactic and Magellanic Cloud PNe. It has provided a powerful online resource for the global community to study both PNe and their CSPN with over 1100 users in more than 60 countries.

In this talk I will present some key, recent results from various HKU based projects on PNe facilitated via our ESO VLT data and HASH. I will cover a recent, enigmatic 5-sigma PNe alignment result in the Galactic centre, our robust abundance determinations, resolution of the decades old “sulphur anomaly” problem and some recent work on PNe in Open Clusters.

Probing the magnetic field orientation of low latitude dark clouds and it's correlation with galactic longitude

Miss Gulafsha B. Choudhury[1], Mr. Bhaskar Goswami[1], Dr. Himadri S. Das[1], Dr. Biman J. Medhi[2], Dr. Jeewan C. Pandey[3]

[1]Department of Physics, Assam University, Silchar-788011 (India). [2]Department of Physics, Gauhati University, Guwahati 781014, India. [3]Aryabhatta Research Institute of Observational Sciences, Manora Peak, Nainital, 263129, India

Abstract

We perform the magnetic field morphology of selected Bok globules and Lynd's clouds situated at low latitudes within the galactic latitude (b) range of −10° to 10°. The polarimetric observations of four clouds, CB17, CB24, CB27, and CB188, were conducted using the 104-cm Sampurnanand Telescope located at ARIES, Manora Peak, Nainital, India, during 22-23 Dec. 2017 and 8th May 2019. The results obtained from the observed data are combined with 13 more low-latitude clouds (*viz.*, CB3, CB4, CB25, CB26, CB34, CB39, CB56, CB60, CB69, CB130, CB246, L1014, and L1415) available in literature. From the polarimetric analysis of 17 clouds, we obtained a correlation between the orientation of the local magnetic field with respect to the galactic plane and their galactic longitude ($\theta_{off} = (0.0020 \pm 0.0006)l^2 - (0.8380 \pm 0.1841)l + (90.5358 \pm 14.09)$, where θ_{off} is the offset between the orientation of local magnetic field of the cloud and the galactic plane) which signifies that the local magnetic field of clouds are oriented along the galactic plane for the clouds that are situated towards the galactic anti-center region and huge offsets are obtained in the clouds that are situated towards the galactic center region. Later, we performed the optical polarimetric analysis of two more low-latitude dark clouds L1495 and L1498, and found that the results fit well with our correlation. We also measured the dust column densities of L1495 and L1498 in both high-density as well as low-density regions of the clouds.

Photometric Light Curve Analysis of Two Contact Binary Systems LS Del and V997 Cyg

Samira Metanat[1], Atila Poro[1], Mehmet Tanriver[2], Laurent Corp[3], Sabrina Baudart[3], Ahmet Bulut[4], Ahmet Keskin[2]

[1]Astronomy Department of the Raderon AI Lab., BC., Burnaby, Canada. [2]Department of Astronomy and Space Science, Faculty of Science, Erciyes University, Kayseri TR-38039, Türkiye. [3]Double Stars Committee, Société Astronomique de France, Paris, France. [4]Department of Physics, Faculty of Sciences, Çanakkale Onsekiz Mart University, Terzioğlu Kampüsü, TR-17020, Çanakkale, Türkiye

Abstract

The light curve analyses and orbital period variations for two W Ursae Majoris (W UMa) binary stars, LS Del and V997 Cyg, were presented in this work. We used TESS data for extracting times of minima and light curve analysis of the target systems. The O-C diagram for both systems displays a parabolic trend. LS Del and V997 Cyg's orbital periods are increasing at a rate of dP/dt= 7.20*10^{-08} d yr^{-1} and dP/dt= 2.54*10^{-08} d yr^{-1}, respectively. Therefore, it can be concluded that the mass is being transferred from the less massive star to the more massive component with a rate of dM/dt=-1.96*10^{-7} M_Sun yr^{-1} for LS Del system, and dM/dt=-3.83*10^{-7} M_Sun yr^{-1} for V997 Cyg. The parameters of the third possible object in the system were also considered. The PHOEBE Python code was used to analyze the light curves. The light curve solutions needed a cold starspot due to the asymmetry in the LS Del system's light curve maxima. The mass ratio, fill-out factor, and star temperature all indicate that both systems are contact binary types in this investigation. Two methods were used to estimate the absolute parameters of the systems: one method used the parallax of Gaia DR3, and the other used a P-M relationship.

First Multiband Photometric Light Curve Analysis of Southern Hemisphere Contact Binary System: DM Cir

Samira Metanat[1], Atila Poro[1], Mehmet Tanriver[2], Ahmet Bulut[3], Ahmet Keskin[2], Mark G. Blackford[4]

[1]Astronomy Department of the Raderon AI Lab., BC., Burnaby, Canada. [2]Erciyes University, Astronomy and Space Science Observatory Application and Research Center, Kayseri TR-38039, Türkiye. [3]Department of Physics, Faculty of Sciences, Çanakkale Onsekiz Mart University, Terzioğlu Kampüsü, TR-17020, Çanakkale, Türkiye. [4]Variable Stars South (VSS), Congarinni Observatory, Congarinni, NSW, 2447, Australia

Abstract

We present the first photometric analysis of DM Cir which is a short period in the Southern Hemisphere. Observations and analysis of this binary system were done in the form of the Binary Systems of South and North (BSN) Project. The ground-based observations were conducted with BVI_c filters. The times of minima of our observations and the TESS sectors' data were extracted, and a new ephemeris was presented. The O-C diagram shows a parabolic trend. According to our computation, the orbital period is increasing at a rate of dP/dt=5.83*10^{-07} d yr^{-1}. The increase of the orbit period can be explained by mass transfer from the less massive component to the more massive one as the mass transfer rate dM_2/dt=-1.01*10^{-6} M_Sun yr^{-1}. We performed a light curve analysis using the Phoebe program. So, the values of mass ratio 0.3932 and fillout factor 29% were obtained. A hot spot on the secondary star was required for the solution. The stars' temperatures indicate that they are a G5 spectral type. The a-P empirical relationship and the mass ratio were utilized for estimating the mass of each star in the system. The other absolute parameters were then computed using standard processes. The results show that DM Cir is an A-type contact binary system. We displayed stars' positions in the M-L and M-R diagrams. In addition, our findings indicate a good agreement with the P-L and q-L_{ratio} empirical relationships.

Reanalyzing the Light Curves of 20 Contact Binary Stars Using TESS Data

Samira Metanat[1], Atila Poro[1], Ehsan Paki[2]

[1]Astronomy Department of the Raderon AI Lab., BC., Burnaby, Canada. [2]BSN Project

Abstract

We revised light curve solutions for 20 W Ursae Majoris (W UMa)-type contact binary systems. We used the latest available Transiting Exoplanet Survey Satellite (TESS) data for analysis. All the analyzed systems have an orbital period of less than 0.58 days and have been introduced as contact systems in previous studies. Light curve solutions were performed using the PHysics Of Eclipsing BinariEs (PHOEBE) Python code version 2.4.9. The results show that systems had various mass ratios from 0.149 to 3.915, and fillout factors from 0.072 to 0.566. The effective temperature of the stars was less than 7016 K, which was expected given the features of most contact binary stars. Twelve of the target systems' light curves were asymmetrical in the maxima, showing the O'Connell effect, and a starspot was required for light curve solutions. The estimation of the absolute parameters of the binary systems was presented using Gaia DR3 parallax. The orbital angular momentum of the systems was calculated. The positions of the systems were also depicted on the L-M, R-M, q-L_{ratio}, and logM_{tot}-logJ_0 diagrams.

Thorne-Zytkow Objects

Professor Christopher Tout

University of Cambridge

Abstract

Thorne-Zytkow objects were envisaged in the 1970s as stars similar to red giants but with the electron degenerate core replaced by a neutron degenerate object. The much increased gravity at the surface of the core likely leads to stars powered by accretion but at temperatures that also support nuclear burning. Full detailed models were made in the 1990s and revealed that hydrogen burning can take place at the base of the star's deep convective envelope at very high temperatures. This allows for proton captures by much heavier charged nuclei. The convective removal of processed material interrupts the burning. In this way TZOs might be responsible for rare p-process isotopes. However the physics, particularly opacities and neutrino loss rates as well as the equation of state, used in these models has been significantly updated in the intervening years. The models also only included hydrogen burning so excluding helium and carbon burning shells and the possibility of thermal pulses. Thus new models are required with more realistic nucleosynthetic yields. It is comparison of abundances with observed giants that offers the best hope of observational identification of a TZO. However attempts to make such models recently have failed. We review the objects, the new physics and the modelling process and attempt to construct our own models.

An Improved Photometric Mode identification Equation for the Light Variation in Non-Radially pulsating stars

Dr Getachew Mengistie[1], Prof Thebe Medupe[2], Prof Thulani Jili[1]

[1]University of Zululand. [2]North-West University

Abstract

In this talk, we introduce a new and improved photometric mode identification formula for pulsating stars. We begin our calculations from the radiative transfer equations. By considering appropriate physical conditions and mathematical formulations, we derive a formula that describes the effect of pulsations in the light output of pulsating stars. For this formulation, we took into

consideration the interaction of light with the different layers of the atmosphere of the star.

The calculation we did is to show the dependence of the variation in the observed luminosity on the surface area, surface normal and variation in temperature which is caused by nonradial pulsations.

By implementing the theories and principles introduced by Watson (1987, 1988), we investigated photometric mode identification and introduce an alternative way of deriving theoretical photometric mode identification. We also demonstrate the effect of pulsation in the light output of a pulsating star. Hence, the calculation we did show the dependence of the variation in the observed luminosity on the surface area, surface normal and variation in temperature caused by nonradial pulsation.

X-Shooting ULLYSES: Massive stars at low metallicity

Prof Jorick Vink

Armagh Observatory and Planetarium

Abstract

Observations of individual massive stars, super-luminous supernovae, gamma-ray bursts, and gravitational wave events involving spectacular black hole mergers indicate that the low-metallicity Universe is fundamentally different from our own Galaxy. Many transient phenomena will remain enigmatic until we achieve a firm understanding of the physics and evolution of massive stars at low metallicity (Z). The Hubble Space Telescope has devoted 500 orbits to observing ∼250 massive stars at low Z in the ultraviolet (UV) with the COS and STIS spectrographs under the ULLYSES programme. The complementary X-Shooting ULLYSES (XShootU) project provides an enhanced legacy value with high-quality optical and near-infrared spectra obtained with the wide-wavelength coverage X-shooter spectrograph at ESO's Very Large Telescope. We present an overview of the XShootU project, showing that combining ULLYSES UV and XShootU optical spectra is critical for the uniform determination of stellar parameters such as effective temperature, surface gravity, luminosity, and abundances, as well as wind properties such as mass-loss rates as a function of Z. As uncertainties in stellar and wind parameters percolate into many adjacent areas of astrophysics, the data and modelling of the XShootU project is expected to be a game changer for our physical understanding of massive stars at low Z. To be able to confidently interpret James Webb Space Telescope spectra of the first stellar generations, the individual spectra of low-Z stars need to be understood, which is exactly where XShootU can deliver.

[3]Institut für Physik und Astronomie, Universität Potsdam. [4]Institute of Astronomy, KU Leuven. [5]Tel Aviv University. [6]Royal Observatory of Belgium. [7]Max Planck Institute for Astrophysics

Abstract

All except one mass transfer episode in the isolated binary evolution channel occur at short timescales and, hence, are difficult to observe. This leads to many unconstrained assumptions in modelling mass transfer phases. The uncertainties percolate through our understanding of progenitors of stripped-envelope supernovae and gravitational wave mergers. As the only exception, the nuclear-timescale so-called 'slow Case A' mass transfer phase in short-period binaries has many Algol binaries as observational counterparts. Since a thermal timescale mass transfer precedes the slow Case A phase, in-situ constraints on stellar and binary physics assumptions, such as mass transfer efficiency, tidal strength and internal mixing, can be obtained through population synthesis studies of massive Algols. I will discuss the current state-of-the-art modelling and observations of these binaries and our identification of a novel outcome from this binary evolution channel, namely the 'reverse Algols'. We identified semi-detached binaries where the more massive star transfers mass to a less massive companion on a nuclear timescale. We also found that binary stripping can form Wolf-Rayet binaries on the main sequence with identified observational counterparts. Our population synthesis results predict ~5% of massive binaries (30-90 Msun) in the main sequence from the reverse Algol channel. We derived the predicted distribution of orbital periods, mass ratios, rotational velocities, and surface abundances of these binaries using a grid of ~100,000 detailed binary evolution models at a metallicity suitable for the Large Magellanic Cloud.

BSN Project: First Light Curve Study of the Low Mass Contact Binary V0610 Vir

Ata Narimani[1], Ailar Alizadehsabegh[2], Atila Poro[3], Frantisek Lomoz[4]

[1]BSN Project, Tabriz, Iran. [2]Department of Photonics, University of Tabriz, Tabriz, Iran. [3]Astronomy Department of the Raderon Al Lab., BC., Burnaby, Canada. [4]Variable Star and Exoplanet Section, Czech Astronomical Society, Prague, Czech Republic

Abstract

Photometric data were used to perform the first light curve analysis of the V0610 Vir binary system. Observations and analysis were done in the form of the Binary Systems of South and North (BSN) Project. We extracted the minima from our observations and compiled the literature, which was few. Therefore, we performed computations using the reference ephemeris and presented a new ephemeris and O-C diagram with a linear fit. Light curve analysis was performed using the PHOEBE Python code and the Markov chain Monte Carlo (MCMC) approach. The assumption of a hot starspot was required due to the asymmetry in the light curve's maxima. The analysis shows that V0610 Vir is a contact binary system with a fillout factor of 0.085, a mass ratio of 0.998, and an inclination of 70.65deg. The absolute parameters of the system were estimated based on the Gaia DR3 parallax method. The results show that the system is a low-mass contact binary with a total mass lower than 0.8(M_Sun). The location of the stars was shown in the M-L and M-R diagrams.

Discovery of a Previously Unknown Population of Eruptive Class I YSOs, within Cygnus-X.

Dr Calum Morris[1], Prof Philip Lucas[1], Prof Zhen Guo[2], Dr Mike Kuhn[1]

[1]University of Hertfordshire. [2]Universidad de Valperaiso

Abstract

Eruptive variability is an important mechanism within the accretion history of YSOs. Stars can see accretion rates increase to the order of ~10^-4 solar masses per year during the larger FU Orionis (FUor) events, which can lead to a vast increase in luminosity for durations ranging from a decade to a century. Further understanding of the phenomenon, with particular regard to the frequency of such events, will be useful in constraining the timescales of star formation. It has been theorised (Audard+ 2014) that these events are more common at earlier phases of stellar formation, but this has been a challenge to observationally confirm. To that end, we undertook an examination of Spitzer selected YSOs within the Cygnus-X complex, comparing the time domain behaviour of both the Class I and Flat-spectrum/Class II stars. We report on 70 candidate eruptive variables within these groups, including 12 stars with eruptions longer than 10 years in duration, and 8 with characteristics that resemble the photometric behaviour of FUors. We find the candidate FUors to be an order of magnitude more common among the younger Class I systems than in flat-spectrum and Class II objects. The embedded systems also show MIR colour behaviour that is redder-when-brighter, which contrasts with traditional eruptive YSOs. Finally, we note the unusual long-term rising behaviours for ten Class I YSOs, with rising timescales longer than five years, which is far slower than ~6-12 month timescale for the historical FUor-type objects.

Opportunities for Observing at the CHARA Array

Dr Christopher Farrington, Dr Gail Schaefer, Dr Douglas Gies, Dr Theo ten Brummelaar, Dr Edgar Ligon, Dr Nicolas Scott, Dr Cyprien Lanthermann, Dr Nils Turner, Dr Jeremy Jones, Dr Narsireddy Anugu, Dr Rainer Kohler, Dr Karolina Kubiak

Georgia State University - CHARA

Abstract

The CHARA Array located at Mount Wilson Observatory combines the light of six 1-meter telescopes at optical/infrared wavelengths to achieve milliarcsecond resolution. The Array is used to measure stellar diameters, image stellar surfaces, detect close binary companions, and resolve the structure of circumstellar disks. Recent and ongoing updates to our instrument suite will provide expanded access to imaging with all six telescopes in the V, H, and K-bands and improved sensitivity for fainter objects. Open access time at the CHARA Array is available through the NOIRLab call for proposals. CHARA staff provides assistance to new observers on developing science programs, planning and collecting observations, and reducing data.

The Polstar FUV Spectropolarimetry Mission to Understand the Role of Rotation in Massive Star Evolution

Dr Paul Scowen

NASA Goddard Space Flight Center

Abstract

Polstar combines, for the first time, the complementary benefits of spectroscopy and polarimetry to provide insight into the impact and effect of rotation, mass loss and stellar environment on the evolution of massive stars. Furthermore, it leverages an innovative combination of effective area and time coverage, to reach the diversity of targets necessary to transform our understanding of how massive stars evolve. Detailed knowledge of these bright, yet distant objects, is crucial because massive stars underpin the Baryonic life cycle in galaxies and thereby dictate the return of energy and processed material to the ISM for subsequent generations of stars and planets. *Polstar* will map stellar wind and magnetospheric structures by uniting time domain, polarimetry and spectroscopy capability in the near- and far-UV (NUV and FUV) which is densely populated with high-opacity resonance lines encoding a rich array of diagnostic information. The instrument combines advances in high reflectivity UV coatings and delta-doped CCDs with high quantum efficiencies to provide dedicated FUV spectropolarimetry for the first time in 25 years. The instrument covers 122-320nm at resolution R~10k. The instrumental polarization stability is built to provide signal-to-noise ratios (SNR) for UV polarimetry precision of $1x10^{-3}$ per exposure per resolution element (resel). Precision can be further improved with spectral binning and/or stacking multiple exposures. *Polstar* spectral resolution is >10x better than WUPPE, with 10x better effective area, while reaching shorter wavelength than *WUPPE* to access strong lines of species like NIV and SiIV.

[5]Laboratoire d'astrophysique de Bordeaux, Univ. Bordeaux, CNRS, B18N, all ´ee Geoffroy Saint-Hilaire, F-33615 Pessac, France

Abstract

In spite of the key role that high-mass stars play in the evolution of galaxy, their early formation processes remain poorly understood due to their complex environment. Dust continuum and molecular line emissions observed with ALMA provide better understanding of the earliest stages of massive star formation. The continuum and spectral lines archival ALMA data of G358.46−0.39 was analyzed using the CASA package in other to probe the gas kinematics and protostellar nature of the ongoing high-mass star formation. The dust continuum map reveals multiple dust continuum cores (MM1a, MM1b, MM1c and MM2) dominated by MM1a. MM1a is found to harbour a periodic methanol maser while MM2 hosts a non-periodic methanol maser and is associated with faint free-free emission. We calculated the masses and the column densities of the various objects (MM1a, MM1b, MM1c and MM2). A total of 33, 10, 10 and 9 molecular transitions are detected towards MM1a, MM1b, MM1c and MM2, respectively. The differences in the number of molecular lines detected towards each of the cores support different excitation conditions at different positions. We derived the kinetic temperature ranges of MM1a, MM1b, MM1c, and MM2 to be $\sim 96 - 118$, $96 - 114$, $72 - 74$, and $80 - 84$ K, respectively. A highly collimated bipolar outflow traced by CO emission is seen towards MM1a, with knots along the outflow lobes, which could be an indication of episodic ejection. The velocity field map of CH_3OH suggests the presence of a rotating structure, possibly a disc. These results are clear indication that MM1a is a massive young stellar object, with ongoing outflow activity.

Binary stars from optical long-baseline interferometry

Dr Alexandre Gallenne

Universidad Andres Bello. French-Chilean Laboratory for Astronomy

Abstract

The most fundamental stellar parameter, the mass, is rarely available or has a low accuracy, providing poor constraints on the stellar structure and evolution. Observing binary stars by combining interferometry and spectroscopic measurements offers a unique opportunity to measure very precise dynamical masses. In addition, double-lined spectroscopic binaries provide independent distance measurements with an extreme accuracy, allowing to direclty test the Gaia parallaxes and the P-L relations of Cepheids. I will show that masses and distances as high as 0.05% accuraccy level can be obtained by combining interferometric and spectroscopic observations for different type of binary systems, i.e. binary Cepheids, eclipsing and normal binaries.

PROBING STRUCTURAL PARAMETERS OF THE GLOBULAR CLUSTER M2 BY ELLIPSE FITTING OF ITS STELLAR DENSITY

PhD student Svetoslav Botev, Assoc. prof. Petko Nedialkov

Department of Astronomy, Sofia University, Bulgaria

Abstract

The Globular cluster M2 is a suitable object for measuring structural parameters like its center's coordinates, ellipticity, and positional angle. Earlier we measured them by elllipse fitting of the 2D spatial distribution of cluster stars, selected within different color-magnitude ranges on HR-diagram. We used g&r photometry from Pan-STARRS Catalog DR1 (Chambers et al. 2016) with a limiting magnitude of V~21 mag. Recently we apply the same technique on of BV photometry of Lee et al. (1999) which goes deeper up to V~22.5 mag. Here we make use of the astrometric part of same data to produce a 100x100 px^2 stellar density map averaged over area of 12x12 $arcsec^2$ and apply elllipse fitting of isodensity pixels. Thus we were able to derive not only more precise estimates of the structural parameters themselves, but also their errors and their variance with the distance from the center of M2.

Resolving the prestellar molecular clumps in the external galaxies

Dr HA Lawal[1], Ms Muhammad Fauziyya Auwal[2]

[1]AFIT Institute of Technology Kaduna Nigeria. [2]Kaduna State University

Abstract

ABSTRACT

In the distribution of molecular mass across the Milky Way Galaxy, dense molecular clumps are the sites where the gas begins its gravitational collapse and produces new stars. We aimed to study the lifestyle of molecular clumps, the formation of clumps and clump masses, clump decomposition and viral theorem. In resolving the pre-stellar molecular clumps in the external galaxies, This method and observations were obtained with the Mopra1 radio telescope, including the configuration of the MOPSspectrometer, which collects data simultaneously on multiple transition within an 8-GHz segment of the 3-mm band is to obtained on resolving the molecular clumps in external galaxies, Mopra is used to collect data on several 'dense gas tracer' spectral lines in the 85–93 GHz range.

The habitability of exoplanets based on the interaction of magnetized protostellar winds

Ms. Yasmmin Tamburus, Ms. Natalia Fernanda de Souza Andrade, Mrs. Vera Jatenco-Pereira

Institute of Astronomy, Geophysics and Atmospheric Sciences - IAG, University of São Paulo, Brazil

Abstract

Strong magnetized stellar winds are observed in weak-lined T Tauris stars (wTTs), where, together with turbulence, can excite MHD modes, like Alfven waves. A possible mechanism for accelerating this wind is their damping. We aim to study the interaction of these magnetized winds with the magnetospheres of Earth-type planets in the habitable zones of their host stars, and verify if their magnetospheres can preserve the planetary atmospheres, acting as a shield. In our model, we assumed a simple constant damping and a non-linear damping. Finally, we obtained our preliminary results that some planets can sustain their atmospheres.

Weird Binaries Under Surveillance: TU Tau and HD 5501

Christopher Corbally[1], Richard Gray[2]

[1]Vatican Observatory. [2]Appalachian State University

Abstract

While TU Tau was known to be a binary (Sanford 1944) with a C-N carbon star primary, it was not until a LAMOST 2013 spectrum was closely inspected by Gray that the companion was revealed as an A2 III-IV star with strong lines of Sr II, Ba II, and Y II. This suggested that it is a prime candidate for a barium giant progenitor. A Pro-Am group began tracking it with photometry and spectroscopy, only to find the companion dimmed irregularly and finally disappeared in April 2023. A trace of the A-giant star was seen in October 2023, so it is clearly serving as a probe of the outer atmosphere of the carbon star.

HD 5501 is an unusual eclipsing binary with a light curve that does not repeat exactly from one cycle to the next. The primary is an A0 II shell star. Photometry and spectroscopy contributed by the same Pro-Am group has detailed the variable emission at H-alpha through a complete phase. The working hypothesis is that the secondary is a B dwarf surrounded by an accretion disk. Mass is being transferred from the primary to the accretion disk, on which there is a hot spot where the mass stream from the primary collides with the disk. Modeling is underway to account more securely for the variations within a cycle and between cycles.

Stellar Physics and General Relativity

Dr Shuichi Yokoyama

Ritsumeikan University

Abstract

As seen in most textbooks of astrophysics, most astronomical bodies such as main sequence stars have been investigated only by Newtonian gravity. This is presumably based on a belief that Newtonian physics could be sufficient to extract important physics of most astronomical bodies except compact stars and General Relativity would be too precise to analyze them.

In this talk, I will explain that this belief is not correct any more and General Relativity plays an important role in extracting new physics of luminous stars like the Sun.

I will explain it based on my recent work arXiv:2306.16647, in which I have investigated the relativistic extension of the classic stellar structure equations and proposed a closed set of differential equations as the basic structure equations for a relativistic hydrostatic equilibrium system with spherical symmetry.

The following characteristic results will be explained as much as possible within given time:

(i) The proposed structure equations are consistent with the expected local thermodynamic relation.

(ii) The exact forms of the relativistic Poisson equation and steady-state heat conduction equation were derived.

(iii) They were solved exactly or non-perturbatively in the Newton constant for a system consisting of an ideal gas of particles with their number conserved, and thermal observables were exactly determined to exhibit the power law behavior.

(iv) This power law behavior is expected also inside the Sun, which is in tension with results in textbooks.

(v) The conventional argument using the Newtonian approximation in coronal region is invalid.

Ensemble analysis of main-sequence stars in the mass transition zone: impact of stellar model physics on the nature of stellar cores

Dr Benard Nsamba

Kyambogo University. Max Planck Institute for Astrophysics

Abstract

Main-sequence stars in the **mass transition region** where their cores may become convective offer an **excellent opportunity of testing our understanding of stellar model physics**. The treatment and implementation of stellar model physics *(such as convective core overshoot and atomic diffusion including gravitational settling)* in models with small cores has significant impact on the nature and size of stellar cores of stars in this region. In this talk, I showcase our findings which entail a **detail analysis of an ensemble of binary stars in the mass transition region**, with known orbital and stellar parameters (such as dynamical mass and radius). These parameters offer additional constraints on our optimisation routines, **allowing to isolate the effects** of convective core overshoot and atomic diffusion on the nature of stellar cores.

The radio evolution of supernova in M82 Galaxy

Dr. Naftali Kimani

Kenyatta University

Abstract

This work report on multi-frequency Very Large Array (VLA) and Very Long Baseline Interferometry (VLBI) radio observations for a monitoring campaign of supernova SN 2008iz in the nearby irregular galaxy M82. The light curve evolution analysis show flux density flares at 970 and 1400 days which are a factor of 2 and 4 higher than the expected flux respectively. The spectral index analysis for frequencies 1.4 to 43 GHz for the period 430 to 2167 days after the explosion show no signs of evolution and remains steep at approximately -1. The high resolution 4.8 and 8.4 GHz VLBI images show supernova expansion start with shell like structure that gets more and more asymmetric, then breaks up in the later epochs with bright structures dominating the southern part of the ring. This structural evolution differs significantly from SN 1993J, which remains circularly symmetric over 4000 days after the explosion. From the energy equipartition between magnetic field and particles, we estimate the minimum total energy in relativistic particles and the magnetic fields during the supernova expansion and found the magnetic field amplification factor for SN 2008iz to be in the range of 55 to 400.

Using Machine Learning algorithms to extract globular clusters in *Gaia* DR3

Mr Nhlengani Junior Baloyi

University of South Africa

Abstract

Star clusters are the building blocks of galaxies, the continued study of which will likely reveal key insights into the chemical, and kinematic properties of galaxies, stellar formation and evolution, as well as assist in applying constraints on dark matter and initial mass function models.

The automated search, spatial and kinematic characterisation of globular clusters (GCs) is carried out through the use of machine learning methods which employ high-precision astrometric and photometric data from Gaia DR3.

Two clustering algorithms, DBSCAN and HDBSCAN, were applied to 24 cone-searched regions containing known GCs. The resulting astrometric parameters were compared to those reported in the literature. The best-performing algorithm was applied to an expanded blind search. The classification of true physical clusters and spurious over-densities was done via a convolutional neural network.

HDBSCAN out-performed DBSCAN by recording a better re-detection rate. For most clusters, the derived astrometric parameters were in agreement with those in literature. The expanded search field contained 18 known GCs. 15 of them were detected, as well as 2 known OC and 57 potential candidates. The masses of GCs M72 and NGC 6397 were derived via a projected mass estimator.

While the methods used here require refinement, their applicability to this science case seems valid. Due to the dearth of GC mass measurements using Gaia data, there is an opportunity for such work to be done, and may assist in the search of the elusive class of intermediate mass black holes.

BSN Project: Analysis of Orbital Period and Light Curve of the V801 And Contact System Using Ground-Based and TESS Observations (Poster)

Ata Narimani[1], Ailar Alizadehsabegh[2], Atila Poro[3], Coliac Jean francois[4]

[1]BSN Project, Tabriz, Iran. [2]Tabriz University, Tabriz, Iran. [3]Astronomy Department of the Raderon AI Lab., BC., Burnaby, Canada. [4]Société astronomique de France, Paris, France

Abstract

We performed the first photometric study of the V801 And W Ursae Majoris (WUMa)-type system based on ground-based and TESS observations. We extracted times of minima from the observations and proposed a linear ephemeris using a Markov chain Monte Carlo (MCMC) approach. The PHOEBE Python code and the MCMC approach were used for the light curve analysis. This binary system needs a cold starspot for the light curve analysis. We also estimated the absolute parameters of the system using the Gaia DR3 parallax method. Therefore, the masses, radii, and luminosities have been determined. The orbital angular momentum of the V801 And system indicated that this system is in a region of contact binaries. The positions of the primary and secondary components on the Hertzsprung-Russell (HR) diagram are depicted. The observations and analysis of V801 And were done in the form of the BSN Project.

Introducing the BSN project in the field of binary star systems

Atila Poro[1], Mark G. Blackford[2], Edwin Budding[3]

[1]The Raderon AI Laboratory, Astronomy Department, BC., Burnaby, Canada. [2]Variable Stars South (VSS), Congarinni Observatory, Congarinni, NSW, 2447, Australia. [3]Carter Observatory, New Zealand

Abstract

Binary Systems of South and North (BSN) project started in 2021. The founders of this project were Atila Poro, Mark G. Blackford and Edwin Budding. So far, this project has collaborated online with 19 observatories in the southern and northern hemispheres for observations and 23 researcher for data analysis. During the last three years, this project focused on contact binary systems, and from 2024, other types have been added to the scope of this project's activities. We held our first meeting in Paris in November 2023 in collaboration with the French Astronomical Society. Perhaps one of the most important current activities of this project is the binary systems analysis software called BSN software. In this presentation, we will present the most important activities along with the introduction of our colleagues (observatories and analysis team). The BSN Project's website: https://bsnp.info/

Investigating the Astrosphere of λ Cephei: Effects of Relative Velocity and ISM Magnetic Field Strength

Mr Douglas Moyeni

North West university center for space science

Abstract

Astrospheres are bullet-shaped structures resulting from the relative motion through the interstellar medium and comprise of three distinct features: a termination shock, astropause, and a bow shock. This work investigates the astrosphere of λ Cephei. λ Cephei is a bright runaway star. Previous 3D magnetohydrodynamic (MHD) simulations by Baalmann et al. (2021) showed the position of the termination shock (TS), astropause (AP), and bow shock (BS) of λ Cephei. A comparison between the simulations by Baalmann et al. (2021) is done using the Pen et al. (2003) model which shows similar results. Due to the Pen et al. (2003) model excluding the radiative cooling process also being solved on a Cartesian grid, the bow shock width is somewhat different compared to the Baalmann et al. (2021) model. Additionally, the study shows how variations in relative velocity and interstellar medium (ISM) magnetic field strength affect λ Cephei's astrosphere. Decreasing relative velocity from 80 km/s to 40 km/s leads to an enlarged astrosphere, particularly evident in bow shock regions. Investigation of ISM magnetic field effects shows that increasing field strength alters the astrosphere's structure, resulting in an asymmetry under high ISM magnetic field conditions.

Massive and/or Magnetic : That is the question.

Dr. Atsuko Nitta[1,2], Prof. Kepler Oliveira[3], Dr. Kathleen Labrie[1], Dr. Scot Kleinman[4], Dr. Andre-Nicolas Chene[5]

[1]Gemini Observatory/NOIRLab. [2]Subaru Telescope, NOAJ. [3]Departmento de Astronomia do Instituto de Física da UFRGS, Brazil. [4]Astronomanger LLC, Hilo HI U.S.A.. [5]US Extremely Large Telescope Program/NOIRLab

Abstract

We seek to understand the origin of magnetic fields in white dwarf stars. One telling clue in this mystery is that spectroscopic mass determinations for magnetic white dwarf stars are consistently higher (averaging ~0.93 Msun) than for non-magnetic white dwarf stars (approximately 0.6 Msun). Since the effects of Stark pressure broadening, an indicator of log(g), or mass, and Zeeman-splitting, from magnetic fields, can mimic each other at low signal to noise, we need to explore this clue in more detail. Are magnetic white dwarf stars really more massive, or do they just appear so? Through our Sloan Digital Sky Survey white dwarf catalog, we identified over a thousand magnetic white dwarf stars over a wide range of field strength, mass, and temperature. The survey data often have low S/N spectra, leaving some uncertainty in our identifications of magnetic fields and hampering our ability to simultaneously measure both the Zeeman-splitting and the Stark pressure broadening in these stars. We therefore used Gemini Observatory's twin 8 meter telescopes to obtain new S/N>70 spectra of a sample of 25 low-field, massive magnetic white dwarf stars to test our low S/N determinations of mass and magnetic field strength. Our results help us understand if these magnetic fields are likely developed through the white dwarf stars' surface convection zones or inherited from massive Ap/Bp progenitors.

Evolutionary models for the most massive stars known in the Universe

Dr Zsolt Keszthelyi

National Astronomical Observatory of Japan

Abstract

30 Doradus in the Large Magellanic Clouds hosts the presently known most massive stars, namely R136a1, R136a2, and R136a3. Spectroscopic studies allow for inferring current masses of the order of 200 - 300 Msun for these stars. Interestingly, close companions are not found around the objects, indicating that they are presently evolving as single stars. We utilize a recent spectroscopic study to adopt mass-loss rates that are constrained for the massive and very massive stars in 30 Doradus. We scrutinize the evolutionary models on the main sequence and beyond and make predictions on the expected supernova and long-duration gamma-ray bursts from various progenitor channels. We compare our new models with the observations of R136a1, a2, and a3 and find compatible single-star solutions. However, an interesting dichotomy emerges as we cannot rule out scenarios in which the initial mass is in the range of 400 - 800 Msun. Within 1 Myr, such stars would lose hundreds of solar masses and appear with similar characteristics as stars with initially 200 - 400 Msun. We conclude that despite their currently very high masses, R136a1, a2, and a3 are unlikely to produce exotic types of supernovae by the end of their evolution. Instead, they are predicted to become extremely hot stars (Teff ~ 100 kK) with final masses of the order of 20 - 40 Msun prior to their explosion.

Search and Study of Variables in Open Clusters and Beyond

Prof. Alisher S. Hojaev

Ulugh Beg Astronomical Institute

Abstract

The determination and understanding of observable properties of stars of different masses and evolutionary stages, their time variability, the physical mechanisms that govern them still remain very relevant. In particular, the search and study of variable stars in star clusters is important not only for studying the variability nature, but also for understanding clusters' physics, kinematics and evolution. We present current results of long-term photometric monitoring campaign of 15 open clusters obtained under the international Uzbek-Indian research project during 2021-2023. Earlier the time series were also obtained for 7 clusters in 2003. Analyzing our data with *TESS* and *Gaia* ones, we discovered a large number of new variable stars as well as checked the few known variables in these clusters and determined their belonging to the cluster (membership), kinematics, distance, age and other parameters of the host cluster. Besides, we also conducted 4-5 hours patrol observations for 14 individual selected magnetic cataclysmic variables (MCVs) in different regions of the sky. In particular, the variables 1RXS J174320.1-042953 and YY Sex have been proven to be magnetic polars. Continuous monitoring of number of selected eclipsing binary stars and of the 2021 outburst of recurrent Nova RS Oph (about 4 months after maximum) were carried out too. The obtained observational database and the current results of its analysis in combination with *TESS* and other data is discussed. Processing and in-depth analysis of this data using original pipelines and existed *BigData* analysis software for *Gaia* and *TESS* is currently ongoing together with Indian partners.

Estimating the maximum mass of an anisotropic star admitting modified Chaplygin gas EOS and prediction of radius of lighter object in GW190814 event

Dr. Pradip Kumar Chattopadhyay

Cooch Behar Panchanan Barma University

Abstract

A new class of model is proposed for relativistic compact stars considering anisotropic fluid distribution. Interior matter is assumed to be satisfy modified Chaplygin gas EOS, $p=H\rho-\frac{K}{\rho^{n}}$, where H, K and n are constants with $0<n\leq1$, and employing Buchdahl-I metric for g_{rr} component within the framework of GR stellar model is obtained. As softer EOS is unable to support massive stellar bodies, a constraint on the EOS must hold. Hence proper choice of EOS may reveal viable information which are consistent with the observational evidences. Recent observations show that observed maximum mass of lighter object in GW 190814 event is approximately $2.59^{+0.08}_{-0.09}~M_{\odot}$ till date. To find the maximum mass in this model, we have solved the TOV equations and noted that the mass of $3.72~M_{\odot}$ is achieved when $H=1.0$, $K=10^{-7}$ and $n=1$. This $3.72~M_{\odot}$ can hardly be obtained in general relativity considering fast rotation effects too. This model is suitable to describe the mass of pulsars PSR J2215+5135 and PSR J0952-0607 and the mass of the lighter component in the GW 190814 event. We consider the pulsar PSR J0740+6620 to study the relevant properties in this approach. All the properties of physical parameters namely, energy density, pressures, and pressure anisotropy etc. are satisfied in this model. To check the physical viability, we have opted for energy conditions and stability analysis. The model satisfies all the necessary criteria to be a physically realistic one.

The oldest stars in the Large Magellanic Cloud

Thomas Nordlander

Research School of Astronomy and Astrophysics, Australian National University

Abstract

The most metal-poor stars alive today carry the chemical fingerprints of ancient stars and supernovae. I will present a resent spectroscopic survey of metal-poor stars in the Large Magellanic Cloud that has uncovered seven of the most metal-poor stars known. Two of the stars are strongly r-process enhanced, with abundances matching the universal r-process pattern. The other five stars are not r-process enhanced, and therefore likely formed before the enhancement event (binary neutron star merger?) discovered by Reggiani et al. 2021, therefore clearly making them both the most metal-poor and oldest stars in this galaxy.

Spectral classification of HD 73574

Dr. Edward JuruA[1], Dr. Otto Trust[1], Mr Gabriel Modo[2]

[1]Mbarara University of Science and Technology. [2]Busitema University

Abstract

Interesting phenomena such as pulsation, rotation, and spot induced variability, have been observed in normal A/F and Am/Fm stars. These phenomena seem to be connected with the chemical anomalies in chemically peculiar (CP) stars. However, the connection between such phenomena and chemical peculiarity still needs to be investigated. Using high resolution spectroscopic observations from Hanle Echelle Spectrograph (HESP), we performed spectral analysis and determined the fundamental atmospheric parameters such as effective temperature, surface gravity, projected rotational velocity, radial velocity, microtubulent velocity, and chemical abundances of HD 73574. From the spectral analysis and the chemical abundance patterns, we classify HD 73574 as Am (kA7hA8mK2) star

Abstract

Photometric variability study provides a unique opportunity to investigate the interplay of processes governing stellar objects. This study presents a comprehensive survey of long-term photometric variability in the intermediate-age open cluster NGC 7209. We conducted V-band photometric observations on over 180 nights, utilizing two telescopes. Our analysis of these observations led to the discovery of more than 280 variable stars within the cluster. 21 of these periodic variables were confirmed as cluster members, while the remaining were classified as field variables. Among the periodic variables, some exhibited short periods (P < 1 day) and others displayed longer periods (P > 1 day). These variable stars demonstrated periodicity spanning from 3.1 hours to 27 days, with brightness ranging from V = 0.053 to 0.764 mag.

Key words: open clusters, variable stars, photometric observations.

[1]Vilnius University. [2]University of Arizona. [3]Vatican Observatory

Abstract

Context. The dynamical evolution of an isolated star cluster is driven by internal, continuous and relatively low-rate mechanisms, and external, episodic and possibly periodic disruption mechanisms. The latter causes some members to detach from the rest of the cluster forming halos and tidal tails. Reconstructing this process should help to determine the main characteristics of the cluster population, such as the initial mass function, as well as refining the Galactic gravitational potential model.

Aims. To construct a set of observable key cluster parameters and interaction signatures that can be compared with dynamical evolution models computed using N-body problem-solving programs.

Methods. Using Gaia DR3 astrometry in combination with available Gaia DR3 broadband photometry and complemented by our observations in the Vilnius medium-band photometric system, we search for previously unrecognized members outside the Hill sphere of known star clusters in Perseus and the Local Arm region.

Results. We present a first sample of the star clusters we have studied, expanding their lists of likely members. Stellar classification using Vilnius photometry data allows us to update estimates of clusters key parameters, including age and extinction, while Gaia astrometry reveals signatures of their dynamical history, e.g. the most recent mass loss event.

Modelling concurrent processes of isolated open cluster disruption: relaxation vs. tidal forces

dr Justas Zdanavičius, Dr Dmitrij Semionov, Dr. Marius Maskoliūnas, Saulius Raudeliunas, Dr Vytautas Čepas

Vilnius University

Abstract

Context. Episodic mass losses in open clusters, due to passage through the Galactic plane or interactions with giant molecular cloud complexes, could significantly accelerate the dissolution of the cluster in the overall disk population, affecting the observed cluster mass function and parameters of the disk's evolution.

Aims. To obtain key parameters such as central concentration (density profile variation), Initial Mass Function and total bound mass by modelling spatial (projected) variation of the cluster mass distribution in the presence of a variable external gravitational potential.

Methods. Starting from a standard (Plummer profile) observed mass distribution, stellar clusters models are evolved up to an age of 1 Gyr using Nbody6 package with varying and constant external potential. Gravitational interaction simulation sets are iteratively adjusted to reproduce the observed spatial and kinematic distribution properties of intermediate-age (10 to 500 Myr) open clusters characteristic of Galactic inter-arm regions.

Results. We present an initial set of models replicating the different evolutionary paths of isolated medium- and low-mass open clusters.

Radiation Vs convection: revisiting the core behaviours of main-sequence stars in the mass transition zone

Ms MARION ASASIRA[1], Dr BENARD NSAMBA[1,2]

[1]Kyambogo University P.o.Box 1 Kampala-Uganda. [2]Max Planck Institute for Astrophysics, Germany

Abstract

The evolution and interior structure of main-sequence stars significantly depends on their core properties. Main-sequence models in the mass range [1.1 -1.2] solar masses and constructed at solar metallicity may develop a convective core during their evolution. We revisit this mass transition zone taking into account the most relevant model physics which affects stellar core properties and chemical profiles, i.e. core overshoot, atomic diffusion including gravitational settling and metal abundance. Our preliminary findings demonstrate that core overshoot and metallicity has the greatest impact in sustaining small convective cores during the main-sequence evolution of stars in the mass transition zone.

A grid-based machine learning tool for inferring exoplanet host-star parameters.

Mr. Juma Kamulali[1], Dr. Benard Nsamba[1,2,3]

[1]Kyambogo University. [2]Max Planck Institute for Astrophysics - Germany. [3]Institute of Astrophysics and Space Sciences - Portugal

Abstract

Uniform inference of exoplanet-host star parameters (such as mass, radius, and age) taking into account the relevant stellar physics is essential in the robust characterisation of planetary systems. This is attributed to the strong synergy between planets and their host-stars. In this poster, we present a machine learning tool which precisely and accurately infers exoplanet host-star parameters, based on available set of spectroscopic constraints. The tool rapidly trains on a set of theoretical model observables, delivering instant estimates of stellar parameters. The results from our machine learning tool are consistent with stellar properties of binary stars, thus can be adopted in uniformly deriving stellar properties of a catalogue of exoplanet-host stars.

Dwarf Cepheids, Classical Cepheids and the PL relation

Dr Clifton D Laney

Western Kentucky University. Brigham Young University. South African Astronomical Observatory

Abstract

Various authors in the past have looked at the possibility that dwarf Cepheids (HADS) can be regarded as small analogues of classical Cepheids (Eggen 1979, Fernie 1992, Laney et al. 2003). It is apparent, however, that the period-luminosity relation for these stars is strongly metallicity dependent (McNamara 1997). I reanalyze the available data to obtain a correlation between metallicity and Stroemgren photometry specifically for dwarf Cepheids, and find that the relation appears to differ from that which applies to non-pulsating stars of similar temperature and luminosity. I then derive a new period-luminosity-metallicity relation for HADS, and compare the period-luminosity relation for solar metallicity to the PL relation for classical Cepheids, both in the visual and in the K-band, using Gaia parallaxes to derive distances. These are corrected for bias as needed (Lutz & Kelker 1973, Benedict et al. 2011, Bailer-Jones et al. 2021).

Re-visiting the masses of retired A type stars

Mr Selassie Karobwa, Dr. Cosmos Dumba

Mbarara University of Science and Technology

Abstract

The detection of planets around bright stars (A, F-type stars) along the main sequence is challenging. This is due to the larger stellar radius and the increased line broadening induced by the faster rotation of these stars. However, the brightness of these stars reduce as they evolve to their sub-giant and low luminosity red-giant phases increasing the detection probability. The characterisation of planets around stars requires robust mass estimates of the hosts. However, the mass estimates of the retired A-type stars using spectroscopic constraints are reported to be overestimated. In this poster, we present a detailed analysis of an ensemble of retired A-type stars while taking into account the available asteroseismic constraints.

Submillimeter observations of the white dwarf pulsar AR Sco

Dr. Paul Barrett[1], Dr. Mark Gurwell[2]

[1]The George Washington University. [2]Center for Astrophysics

Abstract

AR Sco contains a rapidly rotating magnetic white (WD, P_{spin} = 117.0564 s) accreting from a cool, red dwarf companion in a 3.56 hour orbit. It is a strong radio source (~tens mJy) with a positive spectral index between 1—1000 GHz that is indicative of synchrotron emission. We present the first submillimeter observations of AR Sco using the SubMillimeter Array (SMA). The average flux densities at 210 and 354 GHz are 114 and 86 mJy/bm, respectively. The lower than expected flux density at 354 GHz suggests a break in the synchrotron emission at ≈200 GHz. A periodogram analysis of the 210 GHz observations shows a modulation with an amplitude of ≈6% at a period of 58.5595 s or about twice the spin frequency of the WD. This implies that the synchrotron emission arises from interactions of the accreted matter with the WD's magnetic dipole and not from the photosphere of the donor star, which would be modulated at twice the beat frequency. We model the synchrotron emission using an assemble of fast and slow-cooling models and find that observations constrain the WD to have a weak magnetic moment (~10^{33} G cm^3), and not a strong magnetic moment (~10^{35} G cm^3) based on the spin-down power of the WD. A weak magnetic moment avoids the problem of how the WD spun-up to such a rapid rotation rate and then acquired a very strong magnetic field. We conclude that AR Sco is a *magnetic propeller* like AE Aqr.

Grid-based tool for inferring stellar core properties

Mr Ronald Ssembatya[1], Dr Benard Nsamba[1,2]

[1]Kyambogo university, P.O.BOX 1 Kyambogo, Uganda. [2]Max Planck Institute for Astrophysics, Germany

Abstract

Abstract: The proper description of stellar interior physics (such as core overshoot, atomic diffusion) necessities for the revision of the mass transition region where main sequence stars could develop convective cores. We developed a grid-based tool capable of ascertaining the nature (i.e convective or radiative) and properties (chemical abundances, masses, radii) of stellar cores. Our tool relies on comparing radiative and adiabatic temperature gradients in allocating the convective core boundaries. We also test the efficiency of our grid-based tool when the stellar interior physics capable of varying convective boundaries is included in stellar models. We present a revised mass transition region highlighting how each of the essential model physics impacts this region.

Abundances of Bioessential Elements on Solar-type Stars Using High Resolution Spectra

MSc Ellen Costa-Almeida[1], Dr Luan Ghezzi[2], Dr Katia Cunha[3]

[1]National Observatory. [2]Valongo Observatory. [3]Steward Observatory

Abstract

The fast increase in the number of exoplanets detected, associated with an increasingly detailed characterization of exoplanets and their host stars, have expanded the frontiers of Astrobiology and allowed even more comprehensive studies on the formation and habitability of planets and the distribution of life in the Universe. When we think about life as we know it, we are naturally driven to think of the most frequent elements in the composition of organisms: the CHNOPS (carbon, hydrogen, nitrogen, oxygen, phosphorus and sulfur). Though they are bioessential elements for life on Earth, they are not widely explored in abundance studies in general due to challenges in their analyses. Thus, for a better understanding of the structures of planets, habitability and life, it is fundamental to have more homogeneous and precise abundances for these elements for a large number of stars. Therefore, in this work, we derived atmospheric parameters (Teff, [Fe/H] and logg) and abundances O using spectral synthesis and C and S using equivalent widths measured on high-quality spectra and the software MOOG, focusing on solar-type stars with detected exoplanets, in order to investigate the possible relation between these elements and the formation and habitability of planets, to contribute for a better understanding of the necessary conditions for life to emerge. We present homogeneous abundances of Fe, C, O and S for more than 500 solar-type stars and their relationships to the presence of planets.

The Absolute Age of Globular Clusters

Professor Brian Chaboyer[1], Jiaqi Martin Ying[1], Emily Boudreaux[1], Catherine Slaughter[1], Wenxin Du[2], Michael Boylan-Kolchin[3], Daniel Weisz[4]

[1]Dartmouth College. [2]The Ohio State University. [3]The University of Texas at Austin. [4]University of California Berkeley

Abstract

A large set of theoretical isochrones were generated through Monte Carlo simulation using the Dartmouth Stellar Evolution Program. For each isochrone, a range of input physics used in the stellar evolution models, including opacities, nuclear reaction rates, diffusion coefficients, atmospheric boundary conditions, helium abundance, and treatment of convection were varied. Variations in the overall metallicity and α enhancement were also taken into account. These isochrones are used to to measure the absolute age of the galactic globular clusters. We generate simulated Hess diagrams around the main-sequence turn-off region from each set of isochrones and use a Voronoi binning method to fit the diagrams to HST ACS data taking into account uncertainties in the distance and reddening to each cluster. The age of the metal-poor globular cluster M92 ([Fe/H] = -2.2) is 13.8 ± 0.7 Gyr. A similar analysis for the somewhat more metal-rich cluster, NGC 3201 ([Fe/H] = -1.5) finds an age of 11.8 ± 0.9 Gyr. The age of NGC 3201 was also found using via a 2-D KS test in the Hess diagram, leading to a very similar age of 11.6 ± 0.8 Gyr. NGC 3201 hosts 3 eclipsing binaries and fitting the radius, luminosity and masses of these eclipsing binaries with the same set of Monte Carlo generated isochrones yields an age of 12.0 ± 0.6 Gyr. The good agreement of these independent age estimates using different observational datasets and fitting methods demonstrates the reliability of our ages. 11.76 ± 0.8911.76 ± 0.89

Compact Stars with Non-Uniform Relativistic Polytrope

Prof. Mohamed Nouh[1], Mrs Mona Foda[2], Mr. Mohamed Shaban[1]

[1]National Research Institute of Astronomy and Geophysics, Helwan, Cairo, Egypt. [2]Cairo University

Abstract

This paper presents new relativistic composite polytropic models for compact stars by solving Einstein field equations simultaneously with the polytropic equation of state to simulate the spherically symmetric, static matter distribution. Using a non-uniform polytropic index, we get the Tolman-Oppenheimer-Volkoff equation for the relativistic composite polytrope (CTOV). To analyze the star's structure, we numerically solve the CTOV equation and compute the Emden and mass functions for various relativistic parameters and polytropic indices appropriate for neutron stars. The calculation results show that, as the relativistic parameter approaches zero, we recover the well-known Lane-Emden equation from the Newtonian theory of polytropic stars; thus, testing the computational code by comparing composite Newtonian models to those in the literature yields good agreement. We compute composite relativistic models for the neutron star candidates Cen X-3, SAXJ1808.4-3658, and PSR J1614-22304. We shall compare the findings with various existing models in the literature. Based on the accepted models for PSR J1614-22304 and Cen X-3, the star's core radius is predicted to be between 50-60% percent of its total radius, while we found that the radius of the core of star SAXJ1808.4-3658 is around 30% of the total radius. Our findings show that the neutron's structure may be approximated by a composite relativistic polytrope, resulting in masses and radii that are quite consistent with observation.

Characterization of the Young Stellar Clusters Collinder 205 and Ruprecht 709

Arthur Magalhães, Prof. Jane Gregorio-Hetem

Instituto de Astronomia, Geofísica e Ciências Atmosféricas da Universidade de São Paulo - IAG/USP

Abstract

Star clusters are characterized as a group of stars formed from the same cloud of gas and dust within the same period of time. For this reason, the stars in a cluster share common characteristics, making them essential objects for the study of stellar evolution. The evolution of clusters can be better understood based on the study of dynamic conditions of the gas associated with the parental molecular cloud, the clustering properties and by the evaluation of the effects due to the presence of ionization sources. In order to compare the characteristics of the cluster members with the conditions of the molecular gas in the cloud where the young stars are associated, our group conducted near-infrared imaging towards the young clusters Collinder 205 and Ruprecht 79, using the SOAR telescope and the Spartan camera. We aim to extract the sources detected in such images and correlate them with complementary data from public catalogs (optical and infrared), following the example of previous studies perfomed by our group in the CMa region and extended to clusters in different regions of the Galaxy. We conducted PSF photometry on the infrared images of the clusters acquired with the H2, Cont.3, and Brγ filters, and extracted their photometric data using the StarFinder software. In addition to the analysis of Spartan images and photometric extraction to create a catalog of detected sources, we are able to identify confirmed members belonging to the cluster through parallax and proper motion analysis, using data from the Gaia DR3 Catalog.

The Role of External Pressure in Low Mass Star-Forming Cloud

Ms. Tigist Simachew, Dr. Gemechu Muleta

Ethiopian Space Science and Geospacial Institute(SSGI)

Abstract

This thesis explores the critical mass required for low-mass star formation within a self-gravitating cloud influenced by external pressure. The study delves into the molecular cloud's critical mass formation under the impact of external pressure, utilizing theoretical modeling to incorporate fundamental equations and assumptions. The research also investigates the external pressure's role in massive star formation processes, analyzing the star formation rate and efficiency of low-mass star-forming clouds subjected to external pressure. The findings indicate that external pressure can either induce cloud collapse or lead to cloud dispersion. The study concludes that external pressure can have a dual effect on low-mass star-forming clouds. When external pressure is present, clouds with a relatively minimal critical mass can collapse and form stars, whereas clouds with out external pressure require a larger critical mass for collapse. Ultimately, the research highlights the significant impact of external pressure on star-forming molecular clouds.

Investigating Maia-like Physical Features in TESS Target TIC 202431888

Ms Lister Kgwatalala[1], Dr Ceren Ulusoy[1], Assoc. Prof Ivanka Stateva[2]

[1]Botswana International University of Science and Technology. [2]Institute of Astronomy with National Astronomical Observatory - Rozhen

Abstract

We present a comprehensive study of the Maia-type TESS target, TIC 202431888, to investigate its physical features. The study focuses on the Maia Phenomenon among B-type stars, which is characterized by multiple high frequencies between the red edge of the β Cephei and the blue edge of the δ Scuti instability strips. It is possible that the high frequencies observed in late B-type stars still lack an explanation based on current knowledge. In addition the current models do not take into account pulsations in either of these two categories, which even add complexity to pulsation models in the upper main sequence. Recent space missions such as Kepler/K2 and TESS play a pivotal role in accurately determining stellar parameters and solving the classification puzzle of Maia Phenomenon among B-type stars. The frequency content of the star was extracted using TESS photometry, yielding several genuine, harmonics, and combination frequencies. The highest peaks occurred at f_1=19.32 d^{-1} and f_2=22.10 d^{-1}. The atmospheric parameters, projected rotational velocity *v sin i,* and chemical abundance of selected elements of TIC 202431888 were determined using ground-based spectroscopic observations obtained with the 2-m RCC telescope at Rozhen Station of the Bulgarian National Astronomical Observatory. The findings indicate that TIC 202431888 complies with Maia-like physical features, except for having low Fe and Mg values compared to solar values.

Observational properties of Short Period Low Mass EBs

Ms. Redait Basznew, Dr. Seblue Humne

SPACE SCIENCE AND GEOSPATIAL INSTITUTE(SSGI)

Abstract

In this work, we have determined the parameters of an eclipsing binary system using the observed parameters from the catalog of the original Kepler data. Also, we used this catalog to determine the evolution of stars in eclipsing binaries and to determine the orbital and physical characteristics of these within the stellar mass range of 0.302 M⊙ to 1.512 M⊙. The parameters that we have performed include the temperature, the primary and secondary luminosities, the total mass, the orbital period, the orbital angular momentum, and the Roche lobe radius of the donor star. We have also examined the internal stellar structure of stars in these systems between the theoretical models of the zero-age main sequence phase and the terminal-age main sequence phase, as well as beyond. The binary stellar evolution models and the observational data from the catalog of the original Kepler field have been used in these computations. We seek to improve our knowledge of stellar systems and the physical mechanisms influencing their behavior by examining and parameterizing the characteristics and evolution of eclipsing binaries. The study's findings will advance the science of stellar astrophysics and offer important new information on the genesis and development of the Eclipsing binary star system.

Modeling the Formation of Thorne-Zytkow Objects: Hydrodynamical Simulations of Neutron Star-Main Sequence Mergers

Lauryn E. Williams[1], Philip Chang[2], Emily Levesque[1], Tom Quinn[1]

[1]University of Washington - Seattle. [2]University of Wisconsin - Milwaukee

Abstract

Thorne-Zytkow Objects (TZOs) are hypothetical hybrid stars with a neutron star at the core of a large, diffuse envelope. TZOs may be formed when a newly formed neutron star is kicked by its supernova into its main-sequence companion. Using a moving-mesh hydrodynamics solver integrated into the parallel-code Charm N-body GrAvity solver (ChaNGa), we conduct a two-parameter study into these ”impact scenarios” focusing on stellar mass and periapsis. Our hydrodynamical simulations show that at sufficiently small periastrons, there is a successful merger of the massive companion and the neutron star, resulting in a dynamically stable TZO**.** The relevance of this work significantly progresses our limited understanding of the physics of the formation for TZOs, as well as setting important constraints on their relative abundance which aids in the observational search for TZO candidates.

New Observational Insights into the Astrophysics of Extremely Metal-Poor O Stars

Grace Telford

Princeton University. Carnegie Observatories

Abstract

Low-metallicity massive stars produce energetic radiation and supernova explosions that shape the evolution of low-mass galaxies, both locally and in the early universe. Theory predicts that these stars drive weaker winds than their higher-metallicity counterparts, with important implications for their evolutionary pathways and endpoints. Yet, open questions remain about the physical driver of metallicity-dependent differences in the nature of the explosions that end massive stars' lives. A fundamental limitation is that very few observations of individual massive stars below 20% solar metallicity (Z_sun) exist to validate stellar models in the very low-metallicity regime. I will present Hubble Space Telescope FUV spectra of three O stars in nearby dwarf galaxies spanning 3-14% Z_sun, which reveal that the two most metal-poor stars are both fast rotators driving weak stellar winds. Combined with with Keck/KCWI optical spectra, these observations provide novel constraints on theoretical stellar mass-loss prescriptions below 20% Z_sun, a crucial ingredient in evolution models for metal-poor stars. I will then describe the Treasury of Extremely Metal-Poor O Stars (TEMPOS), a new Large Treasury HST program that is assembling a comprehensive FUV and optical spectral library across O-star parameter space at ~5-10% Z_sun. These observations will provide the community with a much-needed empirical benchmark for the stellar models necessary to understand stellar evolution and feedback in metal-poor galaxies.

Investigating triggered star formation scenarios in Galactic star-forming regions

Mrs Annarien Headley, Professor James Chibueze

University of South Africa

Abstract

Highly energetic processes like the expansion of a HII region, explosion of a dying massive star can trigger the formation of a new generation of stars in its vicinity. Granted, the formation of every star in the Milky Way cannot be explained by adopting the triggered scenario. Some stars form spontaneously without the influence of an external force. A key probe of triggered star formation in a region is the distribution of the class 0, I, II and II young stellar objects (YSOs) around the region. A shell-like, “onion-layer” distribution of the different classes of YSOs are typical used as indicators of triggered star formation. In this paper, we revisited the case of the Monkey Head nebula using updated catalog of YSOs. We also investigated triggered star formation around the G06.14-0.63, and 2 others star-forming regions. We found clear evidence of triggered star formation in G06.14-0.63 and the presence of a high-energy gamma ray source at the center of the shell.

The Physical Characteristics Based on The Photometric Study of The Close Binary Systems: KIC 2715417 and KIC 6050116

Mr. Mahmoud NegmEldin

Astronomy Department, Faculty of Science , Cairo University, Egypt

Abstract

We present and analyze the light curve data to determine the physical parameters of the two close binary systems: KIC 2715417 and KIC 6050116. The data obtained from the Kepler space telescope in wide band approaching to Johnson V filter. In order to study the variation due to the eclipsing without any effect of stellar activity, we selected the observed data for a short interval within about 10 days. We used the Wilson Devinney code inside the software PHOEBE (v 0.031a) packages to make the photometric analysis of our systems. The photometric mass ratio has been determined using the q-search method for each system owing to the unavailability of the spectroscopic data. Finally, we found the spectral type of each component of our binary systems from their effective temperatures according to the calibration of Morgan-Keenan (MK).

Investigating Star Formation Rates in Spiral Galaxies: Reducing Uncertainties in Key Indicators

Ms. Boitumelo Gaolape, Dr. Rhodri Evans

Botswana International University of Science and Technology

Abstract

Understanding the star formation process in galaxies is fundamental to unravelling the mysteries of galaxy evolution. Spiral galaxies, with their characteristic arms of stars and gas, offer an ideal setting for studying star formation due to their diverse morphologies and ongoing stellar birth. This study focuses on investigating the star formation rates (SFRs) of a sample of several hundred spiral galaxies, aiming to address major uncertainties in commonly used SFR indicators.

In this research, we aim to investigate the star formation rates (SFRs) of a sample of several hundred spiral galaxies, focusing on reducing uncertainties in three commonly used SFR indicators: ultraviolet (UV) emission, total far infrared (FIR) emission, and 1.4GHz non-thermal radio continuum (NTRC). We will utilize the CIGALE SED fitting model to analyze the complete FIR spectral energy distribution and compare the observed results and our models to Monte Carlo radiative transfer models of dust absorption, scattering, and emission.

This research work provides much better constraints on the fraction of the total FIR emission of galaxies due to star formation. Additionally, we will use this improved modelling of the FIR to gain a more precise understanding of how much UV radiation from hot young stars is lost to dust heating.

Multi-wavelength Monitoring of Two Gamma-ray Binary Stars: 1FGLJ1018.6-5856 and LMC P3

Mr Masekamisha Andries Mathiba

University of Cape Town

Abstract

Gamma-ray binaries are a subclass of high-mass binary systems consisting of a compact object (neutron star/black hole) and an O- or B-type stellar companion. They emit across the electromagnetic spectrum, with a characteristic energy spectrum that peaks above 1 MeV. To date, there are only nine objects in this class.

1FGLJ1018.6-5856 and LMC P3 were discovered in 2011 and 2016, respectively. We are using observational radio data from *MeerKAT* and archival X-ray and Gamma-ray from *Swift* and *Fermi* space telescopes to study these two sources. The main objective of the study is to:
i) Conduct a radio analysis for these sources,
ii) Infer the localization of the multi-wavelength emission and whether it is produced by the same set of particles.

The results of the study will shed light on the dominant emission mechanism in the sources, which will provide evidence about the type of compact object in these binaries (i.e., whether we have a neutron star or black hole).

Monitoring the large-scale magnetic field for active M dwarfs with SPIRou, ESPaDOnS and Narval: the case of AD Leo, CN Leo, DS Leo and EV Lac

Dr. Stefano Bellotti

Leiden Observatory (Leiden, NL). Institute de Recherche en Astrophysique et Planetologie (Toulouse, FR)

Abstract

One clear manifestation of dynamo action on the Sun is the 22-yr magnetic cycle which sees polarity reversals of the large-scale magnetic field. Despite we have some evidence of cycles on other sun-like stars, low-mass, cool M dwarfs are still an unexplored territory. With a long-term spectropolarimetric monitoring of active M dwarfs, we can trace the long-term evolution of their large-scale magnetic field and hunt for magnetic cycles. These observational constraints provide valuable information for dynamo theories and a better understanding of the processes that generate magnetic fields in the interior of stars. For instance, these observations feed back on the dichotomy of magnetic field topologies for fully-convective stars, potentially shedding more light on whether this phenomenon is due to dynamo bistability or the existence of magnetic cycles.
We analysed optical (ESPaDOnS and Narval) and near-infrared (SPIRou) spectropolarimetric data of four well-studied M dwarfs: AD Leo, CN Leo, DS Leo, and EV Lac. We used circularly polarised spectra collected over a baseline of 15 years and reconstructed the large-scale magnetic topology with tomographic inversion (Zeeman-Doppler Imaging). We found different long-term trends, that exhibit similarities or complementarities with the solar cycle, in the form of evolving poloidal-to-toroidal energy fraction, oscillating axisymmetry, and sinusoidal variations of the field strength. This potentially indicates a underlying variety of dynamo processes in action.

Time-series NIR spectroscopy of classical Cepheids

Scott Call[1], Eric Hintz[1], Steve Ardern[2], Victoria Scowcroft[2], Tim Morrell[1]

[1]Brigham Young University. [2]University of Bath

Abstract

Over 100 years ago, Henrietta Leavitt discovered that Cepheid variable stars followed a period-luminosity relation, and to this day, they play a crucial role in the cosmic distance ladder. At near-infrared (NIR) wavelengths, the Cepheid period-luminosity relation is tighter, and interstellar extinction has less impact. NIR data can still be obtained using ground-based observatories, making the NIR regime popular for the study of Cepheids.

In this study, we present time-series spectra for several classical Cepheid variable stars. The data were obtained using the Astrophysical Research Consortium (ARC) 3.5-m telescope and spectrograph, *TripleSpec*, located in New Mexico, USA. The targets range in pulsation period from less than 6 to more than 25 days. Our analyses focus on the molecular features CO (2.3-micron) and CN (1.1-micron) for the sample, specifically examining the dissociation and recombination of these simple molecules throughout the pulsation cycle. Additionally, we conducted static atmosphere fitting and determined NIR colors for the phased observations.

Towards the Understanding of the Largest White Dwarf Evolution Mystery, the DB Gap

Dr. Atsuko Nitta[1,2], Dr. Judi Provencal[3], Kaylee Grace[3], Zachery Savery[3], Dr. Scot Kleinman[4]

[1]Gemini Observatory/NOIRLab. [2]Subaru Telescope, NAOJ. [3]Department of Physics and Astronomy University of Delaware Newark DE 19716 U.S.A.. [4]Astronomanger LLC, Hilo HI U.S.A

Abstract

We present our analysis of Hubble Space Telescope (HST) spectra of two unique DB white dwarf stars to enhance our understanding of general white dwarf (WD) composition and evolution.

WDs, the most common end products of stellar evolution, offer crucial insights into the Milky Way's history via their distribution, structure, and composition. Post internal nuclear fusion, the dominant process in WD evolution is secular cooling. One of the variables that determine the cooling rate is their atmospheric composition. The majority of WDs have either essentially pure hydrogen (DA) or helium (DB) outer atmospheres and the ratio of DA to non-DA WDs varies with temperature, i.e. cooling time.

One outstanding mystery in WD research is the origin of the DB gap, a temperature range in which DBs are notably absent (~45,000 to 30,000K). WD structure and evolution models are heavily influenced by having to explain this gap. Although the Sloan Digital Sky Survey identified a few DBs within this gap, their properties remain poorly understood, and the gap remains at least a dearth if not an outright *gap*.

To explore the DB gap further, we obtained UV spectra of two DBs in the gap using the HST. We present our preliminary analysis of these spectra and what they provide on the physical properties and chemical abundances of these enigmatic objects. Ultimately, we hope to refine our understanding of WD formation and evolution, enhancing our grasp of the WD population and stellar end-stage processes through this and similar analyses.

Statistical analysis of Algol-type eclipsing binaries with stable mass transfer

Dr Seblu Negu

Space Science and Geospatial Institute

Abstract

In this study, we have investigated the stellar parameters of Algol-type eclipsing binaries in the range of primary and secondary masses between 0.2 and 8 M⊙, which were obtained from the catalog of approximate photometric and absolute elements of eclipsing variable stars. We examined those parameters for classical Algols and hot semidetached binaries. We have made a statistical analysis of Algol-type eclipsing binaries' stellar parameters and constructed the mass–luminosity and mass–radius relations for the primary and secondary components of classical Algols and hot semidetached binaries.

Classification techniques for high-mass interacting binary systems. Use of cross validation.

Mr. Rafael Girola Schneider

Universidad Nacional de Tres de Febrero. Planetario Galiuleo Galilei

Abstract

In high-mass interacting binary systems, one can find, for example, binary systems with a compact object (such as a black hole or a neutron star) and a giant star, where both orbit around each other in a very short period. generating intense radiation emissions, which include radio waves, X-rays, and gamma rays, in addition to producing relativistic jets. In this field, there is already an important classification. However, we can ask ourselves from the knowledge of the physical laws and interaction scenarios between the components, which other possible candidates could exist without having been resolved yet, using cross-validation. This technique designed to solve machine learning problems, through regression and prediction models, can be used to evaluate the results of a statistical analysis when the data set has been segmented into a training sample and a test sample. The classification problem involves modeling these systems using training data and then evaluating the model on a test sample. The comparison between the model results and real observations allows us to validate its performance in terms of error, through the hold-out process. The complement of the taxonomy of binary star systems must be self-consistent and logical in relation to what is already known. Therefore, there could be room to discover new classifications even in those cases that have not yet been identified. Continued exploration and detailed study of these systems will allow us to better understand their diversity and evolution.

[1]IAG - University of São Paulo, Brazil. [2]University of Toledo, USA. [3]LESIA, Paris Observatory, Sorbonne University, France. [4]Massachusetts Institute of Technology, USA. [5]SOAR Telescope/NSF's NOIRLab, Chile. [6]Brazilian Astronomic Society, Brazil

Abstract

With its two stellar eclipses and two disk attenuations per binary orbit, V 658 Car stands out as a unique system. Using a new ray-tracing code, we have determined its status as the second known late-type Be + stripped star, occupying a unique niche in the rapidly rotating binary population. Such systems are most likely the sub-product of binary interactions, where the current stripped star has donated its outer layers to a previous normal B star companion. This process spins up the B star into a state of near-critical rotation, triggering mass loss and the subsequent build up of a gaseous circumstellar 'decretion' disks, thus turning it into a classical Be star. As radiation from the stripped star passes through the disk of the primary, the local disk properties are encoded in the observed spectrum. This offers the unique possibility of mapping the disk conditions, as well as the physical characteristics of the stars, with exquisite details. Our study allowed us to identify a series of interesting phenomena that can be attributed to binary interactions, e.g., spiral density waves in the primary disk and mass transfer into the secondary, with the clear detection of circumstellar matter in a disk-like configuration surrounding the stripped star. A full analysis promises to make this a benchmark system, with properties determined with far higher precision than what is typically possible.

Unveiling Starspot Penumbra from Exoplanet Transit Photometry

Prof Adriana Valio[1], Dr Shelley M. Zaleski[2], Prof. Brad D. Carter[2]

[1]Center for Radio Astronomy and Astrophysics Mackenzie, Mackenzie Presbyterian University, São Paulo, Brazil. [2]Centre for Astrophysics, University of Southern Queensland, Australia

Abstract

While current methodologies map large-scale starspots on rapidly rotating active stars, investigation of active regions structure on slowly rotating, solar-like stars is challenging. For this, we introduce a novel analysis technique aimed at extracting the umbral and penumbral structure of starspots from exoplanet transit light curves. Our goal is to determine the constraints associated with penumbra detectability. Our method uses simulated transits of a solar active region to determine the resulting flux ratios of occulted umbra and penumbra. The detection of starspot penumbrae depends on their flux variations in transit light curves surpassing the photometric noise. This detection threshold is related to the apparent stellar magnitude, as noise predominates for all but the brightest stars. Thus, a large transit depth is crucial for detection, albeit the penumbra potentially becoming undetectable due to low contrast relative to the photosphere in the case of the coolest stars. For systems featuring a 2 or 3 R planet transiting an M or small K dwarf star, low-contrast (high-intensity) penumbrae may be discernible for stars with Mv ≤ 13. This shows the feasibility of detecting stellar umbrae and penumbrae with flux ratios similar to solar values (1.7 - 4.4). Consequently, we demonstrate that future space-based transit photometry may provide characterization

Stellar Archeology of the Be + sdO Binaries

Dr. Geraldine Peters

University of Southern California

Abstract

Currently there is a consensus that at least 50% of the OB stars evolve as close binary systems. The recent discovery that many Be stars have an sdO companion reinforces the widely held perception that the classical Be stars acquired their fast rotation and resultant disk through mass transfer. The Be star has been spun up from the mass and angular momentum gained and the sdO object is the core of what remains of the mass loser. The details through which the Be star acquires and distributes its acquired mass and angular momentum are currently mostly speculative. We have embarked on an effort to identify proxies of the Be + sdO binaries in their earlier lives to gain an insight on their progenitors and information on the mass transfer process itself such as if it is conservative or if there are important epochs of non-conservative mass transfer. The data for this study are primarily archival high-resolution FUV spectra from the *IUE* and *FUSE* spacecraft. The procedure is to track the evolution of the mass gainer in the r-q Diagram (RQD). Massive Algol-type systems appear to be younger versions of the Be + sdO systems. Early results reveal that systemic mass loss is largest when the system is passing through Region 2 of the RQD, whereas mass and angular momentum transfer are mostly conservative in the upper part of Region 1. Details of the evolution of the mass flow structures (gas stream, disk, and mass outflow regions) are given in this presentation.

A simple method using the derivatives of light curves for estimating the mass ratios of overcontact eclipsing binaries.

Shinjirou Kouzuma

Chukyo University

Abstract

The mass ratio is a key parameter in overcontact binary systems. A reliable mass ratio is derived from a radial velocity curve through spectroscopic observation. However, this requires relatively advanced instruments and repeated observations. Photometric mass ratios are estimated using light curves, usually obtained through light curve modeling. This method is more convenient compared to deriving spectroscopic mass ratios. A major downside of this method is that the derivation of photometric mass ratios requires an appropriate parameter setting and light curve modeling with an iterative method.

We propose a new method for estimating photometric mass ratios. Our approach primarily involves measuring the time interval between two local extrema found in the third derivative of a light curve, with no need of an iterative procedure. We validated the effectiveness of our method by comparing the mass ratios estimated by our method with their spectroscopic values. The comparison showed that our estimated mass ratios for ∼67 % of the samples agreed with their spectroscopic mass ratios within the estimated uncertainties, and the errors for 95% of them are within ±0.1. In the presentation, we also discuss the background of why the proposed method works and the influence of third light on our estimation.

RR Lyrae stars as distance calibrator and as tracers of Galaxy kinematics and structure.

Dr Tesfaye Muhie

Washera Geospace and Radar Science Research Laboratory, Physics Department, Science Collage, Bahir Dar University, Bahir Dar, Ethiopia. Institute of Geophysics, Space Science and Astronomy, (IGSA), Addis Ababa University, Ethiopia

Abstract

By studying the multicomponent kinematic model of RR Lyrae stars(RRLs) in the Milky Way using the statistical parallax method, RRLs distance calibration can be improved and insight into the Galaxy structure and evolution can be gained. Though many authors have used the method to set the zero point of the period-luminosity-metallicity-(PLZ) relation of RRLs in differentt bands and to estimate the velocity distribution of the Galactic field RR Lyrae population since its first use; the uncertainties of the estimated parameters are still significant due to the reliant of the method on the sample size and the accuracy of the input observational data. Thus, this research is dedicated on improv the results of the method by increasing the sample size with accurate photometric and spectroscopic data. In the study, I obtained a number of new important results including original BVI photometric CCD observations of 197 RR Lyraes performed with the 1.0-m SAAO telescope and original low-resolution spectroscopic observations of 488 RR Lyraes performed with the 11-m Southern African Large Telescope (SALT). The photometric and spectroscopic results were combined with previously published data including the data from large-scale surveys, and properly homogenized, allowing me to significantly refine previous kinematic model of the Milky Way and their period-luminosity metallicity relationships based on the statistical-parallax method. My analysis actually narrows down the long-time distance calibration gap between the statistical parallaxes method and others. The other new result that was estimated is the Gaia DR2 parallax offset.

[1]South African Astronomical Observatory. [2]Southern African Large Telescope. [3]CAB. [4]ESA. [5]SAAO/SALT

Abstract

High-mass X-ray binaries (HMXB) are one of the most numerous class of interacting binary star systems. They offer the chance to observe extreme physics in high magnetic field and strong gravitational environments, as well as massive stellar and binary evolution, which may ultimately lead to double-degenerate systems. A large fraction of HMXBs comprise a neutron star and a Be star, which is characterised by an equatorial 'decretion' disc from which the neutron star periodically accretes. Studying the interaction between the Be star, disc and compact object is central to our understanding of the formation and evolution of these systems. Whilst X-ray all-sky monitors have built up excellent long-term light curves of the accretion events in HMXBs, our optical coverage, particularly spectroscopic, has been much sparser. We present here details of our 10 year Southern African Large Telescope (SALT) optical spectroscopic monitoring programme of the Be counterparts of Galactic and Magellanic HMXBs. The long baseline of these observations, along with good cadence, resolution & S/N make this one of the best available optical spectroscopic datasets in the field, and a valuable resource for observers and theoreticians alike. We discuss some of the science that our team is doing with this data, and our plans to release the full catalogue to the community.

Spectroscopic properties of microlensing events alerted by Gaia

Pawel Zielinski[1], Etienne Bachelet[2], Mariusz Gromadzki[3], Lukasz Wyrzykowski[3]

[1]Institute of Astronomy, Nicolaus Copernicus University in Toruń, Poland. [2]Caltech/IPAC, Pasadena, California, USA. [3]Astronomical Observatory, University of Warsaw, Poland

Abstract

The Gaia mission delivers enourmous amount of astrometric and photometric data. Based on Gaia light curves we are able to select a growing number of microlensing event candidates located mostly in the Galactic Plane. The majority of them must still be classified spectroscopically in order to distinguish genuine microlensing events from other types of outbursts and variables. Therefore, we use a wide range of world-class telescopes equipped with low- and high-resolution spectrographs to detect distinctive absorption and/or emission features and determine physical parameters as well as line-of-sight extinction for the sources in the microlensing events. Moreover, the spectroscopic analysis is important not only in constraining the microlensing model and the lens parameters, but also in distance estimation. From the comparison of spectroscopic distances with Gaia parallax/distance measurements we found that at least in some cases Gaia distances can not be trusted (probably due to blending or astrometric microlensing) and have to be used with caution. In additon, this seems to be reflected in the quality flags and parameters of astrometric signals given in the GaiaDR3 catalogue. I will present the status of the spectroscopic study of candidates for microlensing events alerted by Gaia with recent examples of interesting results.

Deciphering Super-Metallicity, Lithium Depletion, and Radial Migration in the Vicinity of Our Solar Neighborhood

Dr. Maria Luiza L. Dantas[1,2,3], Prof. Rodolfo Smiljanic[3]

[1]Pontificia Universidad Catolica de Chile, Santiago, Chile. [2]Center for Theoretical Physics, Polish Academy of Sciences, Warsaw, Poland. [3]Nicolaus Copernicus Astronomical Center, Polish Academy of Sciences, Warsaw, Poland

Abstract

We present the discovery of a unique set of super-metal-rich dwarf stars exhibiting low eccentricity orbits, peaking in height from the Galactic plane at ~0.5-1.5 kpc. Utilizing data from the Gaia-ESO Survey, we analyze high-resolution observations of stars with abundances spanning over 18 elements. Employing hierarchical clustering on abundance data (excluding Li), and integrating orbits using Gaia astrometry and Gaia-ESO radial velocities, we estimate stellar ages through isochrone fitting and Bayesian methods. Our investigation reveals five distinct subgroups characterized by a median age of around 8 Gyr, near-solar [Mg/Fe] ratios, varying Galactic azimuthal heights, low eccentricities, and no discernible metallicity gradient with guiding radius. These findings suggest an origin in the inner Galaxy, with subsequent migration to the solar vicinity likely driven by interactions with the galactic bar and spiral arms. Furthermore, our analysis confirms previous observations of sub-benchmark lithium abundance in old metal-rich dwarf stars, challenging its utility as a proxy for interstellar medium lithium. Our study sheds light on the chemo-dynamical properties and origins of these stars, posing intriguing questions about Galactic evolution. For more details, see Dantas et al. (2023, A&A, 669, A96; 2022, A&A, 668, L7).

From Birth to Orbit: Dissecting churn and blur in Galactic dynamics

Dr. Maria Luiza L. Dantas[1,2,3], Prof. Rodolfo Smiljanic[4]

[1]Pontificia Universidad Catolica de Chile, Santiago, Chile. [2]Center for Theoretical Physics, Polish Academy of Sciences, Warsaw, Poland. [3]Nicolaus Copernicus Astronomical Center, Polish Academy of Sciences, Warsaw, Poland Gender of presenter: Female. [4]Nicolaus Copernicus Astronomical Center, Polish Academy of Sciences, Warsaw, Poland

Abstract

As stars traverse the Galaxy, their orbits are influenced by various perturbations, leading to deviations from their original birth radii, which can be attributed to two main mechanisms: "churning," characterized by a change in angular momentum, and "blurring," characterized by a significant change in angular momentum. In Dantas et al. (in prep), we assess the motion of these stars within the context of theoretical chemical evolution models for the Milky Way, enhancing the precision of these models by generating finer grids and delving into the orbital characteristics of a diverse set of Gaia-ESO stars. We employ a Generalized Additive Model (GAM) to estimate birth radii for the stars and compare these predictions with calculated guiding, apocentric, and pericentric radii using the *galpy* in conjunction with Gaia parallaxes. Our analysis involves Hierarchical Clustering of 21 chemical abundances across 18 species to categorize the stellar dataset, quantifying and qualifying perturbations experienced by these stars. Our results reveal that metal-rich stars formed in the inner regions of the Milky Way seem to be moving outwards, and metal-poor counterparts formed in larger Galactocentric radii are moving inwards. We discuss the potential influence of the transient spiral arms and the central bar of the Galaxy. Furthermore, we attempt on quantifying the movement of each star, i.e. either blurring or churning. Finally, we compare our findings with simulations and provide insights into the potential causes of the migration, including the role of the central bar and spiral arms (Dantas et al. in prep.).

HIGH RESOLUTION STUDIES OF THE C-BAND AND L-BANDRADIO CONTINUUM OF THE PERIODIC METHANOL MASERSOURCE G9.62 +-0.20E AND SURROUNDING SOURCES

Dr. Benedicta Woode[1], Prof Melvic Hoare[2]

[1]Ghana Space Scence and Technology institute. [2]University of Leeds

Abstract

High resolution observations of the C and L-band radio continuum of the hyper-compact HII region G9.62 +-0.20E conducted

with the e-MERLIN array are presented. A flux density of 2.25 +-0.20 mJy and an angular size of 127+-22 mas

were measured for the C-band continuum. At L-band, an upper limit of 162 micro Jy on the integrated flux density was calculated at

the position of the continuum. The surrounding sources C and D were detected at levels consistent with previous detections.

The results for source E shows that the upper limit for L-band is not consistent and reveals the spectrum falls off more

steepily from L-band as extrapolated from high frequencies. This can be explained with a truncated inverse square law

density distribution model. The calculated C-band peak brightness temperature of about 4000K, which translates to an optical

depth of 0.5, indicates that the continuum is optically thin at C-band and optically thick at L-band. These continuum results

therefore place firm constraints on models of the HII region in source E. In the context of the colliding wind binary (CWB) model

for the periodic maser it is very small changes in the the seed photons from the background HII region that are greatly

amplified by the maser that explains the maser variability. Hence, models of the H II region that match our observations

can be used to test the predictions of the CWB model in terms of the variability profiles of the 1.6GHz OH

and the 6.7 GHz methanol masers

physical properties of post common envelope binaries and their distribution

physical properties of post common envelope binaries and their distribution AYANA FEKADU

Space science and Geospatial Institute.. Addis Ababa University

Abstract

Post-common envelope binaries (PCEBs) represent a crucial phase in the evolution of binary star systems, characterized by the shedding of a common envelope during mass transfer between the two stars. Understanding the physical properties and distribution of PCEBs is essential for elucidating the common envelope phase, binary star evolution, and the formation of exotic objects such as cataclysmic variables and type Ia supernovae. In this study, we present an analysis of a large sample of PCEBs drawn from observational surveys and theoretical models. We investigate the distribution of key physical properties such as orbital parameters, component masses, spectral characteristics, and evolutionary histories. Our analysis reveals important insights into the demographics of PCEBs, including their mass ratio distribution, period distribution, and the incidence of various evolutionary outcomes. We discuss the implications of our findings for theories of binary star formation and evolution, as well as the potential role of PCEBs in the production of gravitational wave sources. Our results contribute to a comprehensive understanding of post-common envelope binaries and their significance in astrophysical contexts.

A Multi-wavelength Study of the Galactic Point Sources in the SARAO MeerKAT Galactic Plane Survey with Gaia DR3

Okwudili Egbo[1,2], Prof David Buckley[1,2], Prof Paul Groot[1,2]

[1]University of Cape Town. [2]South African Astronomical Observatory

Abstract

The SARAO MeerKAT Galactic Plane Survey is a radio continuum survey conducted in the *L* band (~1.3 GHz) in the Galactic plane, covering a wide range of galactic longitudes, and mostly within a latitude range of $|b| \leq 1.5$ degrees. In this study, we present our analysis of the Galactic stellar sources by cross-matching the radio point sources with the Gaia Data Release 3 (DR3) and the X-ray ROSAT catalogs. To refine our sample and mitigate spurious and extragalactic counterparts, we imposed a selection criterion based on multiple Gaia parameters such as proper motion and distances resulting in a few hundred sources. Leveraging the Gaia extinction measurements along the line of sight and the reddening parameter, we applied extinction corrections to the magnitudes and dereddened the colors of the optical counterpart candidates to produce a color-magnitude diagram (CMD). The CMD revealed a diverse population of stellar sources, ranging from massive OB binaries such as wolf-rayets, main-sequence RS CVn binaries, YSOs and dMe stars. Using distance estimates from Gaia, we calculated the radio-X-ray luminosities for 35 sources with ROSAT associations and obtained radio luminosities in the range of 10^{13} - 10^{17} erg s^{-1} Hz-1. A correlation exist between the radio-X-ray luminosities hence the stars follow the Gudel-Benz luminosity relationship indicating that gyro-synchrotron emission is responsible for the radio emission and as the non-thermal electrons travel through the stellar chromospheres, they lose energy in the process, thereby heating the stellar corona which gives rise to thermal X-ray emission.

Results of a preliminary search for new hot sub-dwarf stars in binaries in TESS

Mr Goutham Anitha Kumari[1,2], Dr Jerzy Krzesiński[1], Dr Murat Uzundag[3]

[1]Astronomical Observatory of the Jagiellonian University. [2]Jagiellonian University, Doctoral School of Exact and Natural Sciences, Faculty of Physics, Astronomy and Applied Computer Science. [3]Institute of Astronomy KU Leuven

Abstract

Hot subdwarf B stars (sdB) are stellar objects at the late stage of their stellar evolution. These helium burning objects are the product of excessive loss of hydrogen envelope before the helium flash. The origins of these objects are believed to arise from binary interactions, with three primary formation channels proposed: common-envelope ejection (CEE), stable Roche-lobe overflow (RLOF) mechanism, and the merger of two low-mass white dwarfs (Han et al., 2002, 2003). These objects are crucial for studying the late stages of stellar evolution, binary interactions, and stellar interiors, particularly through the analysis of their pulsations. Current research indicates that approximately 60% of identified sdB stars are located within binary systems. Depending on the interactions between the sdB and its companion, these binaries are divided into two main groups, the systems with long orbital periods (longer than one year) produced in a stable RLOF, and the short period systems (order of hours) which evolved via the CEE.

Recently, we have published a catalog comprising over 300 variable sdBs (Uzundag et al., 2024). In this poster, we expand our investigation using the latest dataset from Transiting Exoplanet Survey Satellite (TESS) to identify newly discovered sdBs in binaries and pulsating sdB stars. We utilize a sample of approximately 3000 objects obtained from the Gaia EDR3 catalog of potential hot subdwarf candidates (Culpan et al., 2022), cross-matched with TESS data.

Abstract

The B emission-line stars are rapid rotators that were probably spun up by mass and angular momentum accretion through mass transfer in an interacting binary. Mass transfer will strip the donor star of its envelope to form a hot and faint subdwarf star. Here we present our past and present works on detecting and characterizing the hot sdO companions of rapidly rotating Be stars using spectroscopic observations from the International Ultraviolet Explorer and Hubble Space Telescope. Further analysis of such binaries yields the temperatures and radii of the hot sdO stars, a comparison of these measurements to evolutionary tracks indicates that the sdO stars occupy the relatively long-lived, helium core burning stage. By complementing the study with ground optical spectra analysis, we determined the orbital and physical properties of several Be+sdO binary systems and found that the sdO stars in a few of them could be progenitors of Type Ib and Ic supernovae. Continuing long-term monitoring of these Be+sdO binaries to determine their physical, atmospheric, and orbital parameters will provide insights into understanding the formation and evolution of massive stars.

Herbig Ae/Be Stars: Bridging the Gap in Star Formation

Dr Blesson Mathew

Christ University

Abstract

Herbig Ae/Be stars are often considered as the crucial missing link in our understanding of star formation as their mass is intermediate to that of low-mass and high-mass pre-main sequence stars. A strategy to address this problem is to have a multi-wavelength approach, where one could study samples of Herbig Ae/Be stars in diverse environments using missions or survey programs such as Gaia, LAMOST, XShooter, Spitzer and Chandra. With the advent of the Gaia space mission, quite a number of interesting studies were published, where the focus was to evaluate the role of clustering in the immediate environment of Herbig Ae/Be stars. We will also discuss the exciting studies from spectroscopy, particularly with LAMOST, which was instrumental in understanding the accretion mechanisms in Herbig Ae/Be stars. The line profile studies from Xshooter spectra were very much useful to evaluate the dynamics of the circumstellar environment in these young stars. Thanks to missions such as JWST and Spitzer, the formation of molecules in the disk of Herbig Ae/Be stars is being understood in a better manner. We will highlight the astrochemistry studies from our group, particularly those stars with PAH emission and the recent discovery of fullerene molecules in the circumstellar medium of Herbig Ae/Be stars. Finally, we discuss the role of a low-mass companion in Herbig Ae/Be stars, as evident from the X-ray emission seen from Chandra observations.

Accretion processes in cataclysmic variable stars: Insights from optical transient surveys

Miss Mokhine Motsoaledi[1,2], Prof. Patrick Woudt[1], Dr David Buckley[2]

[1]University of Cape Town. [2]South African Astronomical Observatory

Abstract

Cataclysmic variable stars are binary stars mainly characterised by accretion from a main sequence donor star to a white dwarf star. This study focuses on two sub-classes of cataclysmic variables, namely AM CVn stars with helium accretion from a compact (semi-)degenerate donor star and magnetic cataclysmic variables with strong magnetic fields leading to magnetically-controlled accretion. I make use of optical transient surveys, primarily the Catalina Real-time Transient Survey (CRTS), for the identification of individual objects to follow up. I will present some of the spectroscopic and photometric results of individual cataclysmic variables using the 11-m Southern African Large Telescope and the 1.0/1.9-m telescopes situated at the South African Astronomical Observatory in Sutherland, South Africa. I also used the long-term light curves from CRTS to characterise the long-term photometric behavioural patterns of magnetic cataclysmic variables. A set of criteria was developed to quantify these characterisations and to systematically identify potential magnetic cataclysmic variables through their long-term light curves.

Stacking radio stars in MIGHTEE

Francesco Cavallaro

INAF - Osservatorio Astrofisico di Catania

Abstract

The MIGHTEE (MeerKAT International GHz Tiered Extragalactic Exploration) survey has emerged as a groundbreaking initiative, leveraging the unprecedented capabilities of the MeerKAT radio telescope array to explore the depths of the radio sky. Even if its primary focus is on extragalactic sources, MIGHTEE can push forward the study of late-type stars through stacking techniques. .

Stars, typically associated with optical and infrared observations, have been relatively unexplored in the radio wavelength domain. MIGHTEE's unique sensitivity and high-resolution imaging provide an opportunity to revolutionize our understanding of stellar radio emission. By employing the innovative technique of stacking, we aggregate faint signals from individual stars, from the Gaia catalogue in the MIGHTEE region, thereby enhancing our ability to detect and characterize the radio emission from this stellar population.

The presentation will outline the methodology behind the stacking process, highlighting the challenges and advantages associated with probing the radio properties of stars in large-scale surveys. Preliminary results from the MIGHTEE survey will be presented, showcasing the collective radio signatures of stacked stars and providing insights into the underlying physical mechanisms responsible for their radio emission.

Supernovae as reporting messengers about structure and properties of the surrounding universe

Dr. Petr Kurfürst

Masaryk University

Abstract

We study the interactions of expanding envelopes of supernovae (SN) with dense asymmetric circumstellar matter (CSM) of various shapes and profiles, forming a circumstellar disk, bipolar outflows, or slabs of colliding matter ejected in binaries. Various not well understood mechanisms can lead to non-stationary eruptions of huge amounts of matter from SN progenitors, which may be active over a long time or only shortly before the SN explosion. The propagation of a supernova shock wave through such an environment leads to a substantial increase in luminosity and duration of light curves which exhibit characteristic irregularities, including sudden brightenings or fluctuations. These effects can also manifest themselves in significant asymmetries in the spectra when observed from different directions. We have used multidimensional radiation-hydrodynamics codes to simulate the gas dynamics in shock wave regions and quantify the thermal energy of shock waves released during such interactions. Using a 3D radiative-transfer code, we determined the light curves and spectral profiles produced by such SN-CSM interactions, “seen” from different directions at different times. By comparing the calculated observables with the really observed ones, we estimate the amount and spatial distribution of the ejected mass before the explosion. This can further contribute to the description of the distribution of CSM and to the understanding of the mechanisms of violent outbursts or extremely violent eruptions by which this matter is ejected into space from stars approaching their death.

Optical Light Curve and Spectral Analyses of Recurrent Nova RS Ophiuchi during the 2021 Outburst

Dr Nazhatulshima Ahmad[1], Dr Hakim Luthfi Malasan[2], Dr Akira Arai[3]

[1]Universiti Malaya. [2]Institute Technology of Bandung. [3]National Astronomical Observatory of Japan

Abstract

The recurrent nova RS Ophiuchi (hereafter RS Oph) erupted again in August 2021, 15.5 years following the 2006 eruption. Regular monitoring of the eruption by amateur and professional observers, with numerous spectra taken covering a wide spectral range, including optical, UV, and X-rays.

This study analyzed the optical light curve and spectra during its outburst in August 2021 obtained from AAVSO [1] and ARAS [2] databases. The light curve analysis shows that the magnitude change of the RS Oph takes 102 days for the phase of initial rise (explosion) to the final declining phase with the dimmest magnitude of 12.3. The nova eruption period was separated into five main phases according to the light curve variation, in which the brightness increased from magnitude 9.1 to 4.78 within less than 24 hours during its initial rise phase.

From spectral analyses, the initial and maximum brightness phase spectra are dominated by hydrogen line (H-alpha), FeI and ArII in the P-Cygni profile. The expansion velocity of the H-alpha profile during the outburst phenomena rose from 5396.7 ± 2.3 km/s in the initial rise to 7066.3 ± 2.6 km/s a day after its maximum brightness. The P-Cygni profile starts to disappear at the end of the early decline and transition phases toward the final declining phase. Permitted-line phase Based on the element lines present during the phenomena, RS Oph is classified as a fast hybrid nova that evolved from Fe II to He/N class.

Higher-order multipolar magnetic fields of corotating clouds of hot stars

Dr. Petr Kurfürst

Masaryk University

Abstract

We performed 3D magnetohydrodynamic simulations of magnetic fields and surrounding magnetospheres of massive, hot stars. Here, we considered not only the dipole configuration but also the possible higher polarities of these fields. The purpose of these simulations was to to investigate and assess in detail the influence of magnetic fields and stellar magnetospheres using dynamical, that is rotating and evolving over time, models on the abundance and geometric structure of the mass flowing out of these stars into the surrounding space. Determining the mass loss of these stars is crucial for studying the further evolution of both the surrounding environment supplied by this mass and the star itself. The latter, depending on the greater or lesser loss of its mass, may become the origin of cataclysmic objects and processes associated with supernova explosions, gamma-ray bursts or magnetars, leading ultimately to exotic phenomena such as kilonovae or direct collapses of stellar objects into black holes. Thus, the study of the magnetism of massive stars provides a key to better understanding and quantifying the evolution that leads to these phenomena.

Synthetic stellar spectra to study multiple populations in globular clusters: an extended grid and the effects on the integrated light.

MSc Vinicius Branco

IAG/USP

Abstract

Most Galactic Globular Clusters (GCs) harbor multiple populations of stars (MPs), composed of at least two generations: the first characterized by a “standard” α-enhanced metal mixture, as observed in field halo stars of the Milky Way, and the second displaying anti-correlated CN-ONa chemical abundance pattern in combination with an enhanced helium fraction. Adequate collections of stellar spectra are needed to characterize the effect of such stellar abundance changes on the integrated light of GCs. Expanding on previous work, we present a grid of synthetic stellar spectra based on empirical stellar population data, covering the atmospheric parameters relevant to old stellar populations at four subsolar metallicities. Each population was computed} with abundance patterns representative of both a standard α-enhanced metal mixture and one with abundances typical of second-generations of stars in GCs. The spectra extend from 2900 to 10100Å. Using the stellar grid, we synthesized integrated spectra based on color-magnitude diagrams of Galactic GCs and studied the effect of the specific stellar surface abundances of multiple populations in terms of spectrophotometric indices. We find non-negligible effects of the MPs on spectroscopic indices sensitive to C, N, Ca, or Na, and on Balmer indices; we also describe how MPs modify specific regions in the near-UV and near-IR that can be measured with narrow or medium photometric passbands. The effects vary with metallicity. A number of these changes remain detectable even when accounting for the stochastic fluctuations due to the finite nature of the stellar population cluster

Stellar activity an important ingredient for planet habitability: the case of M stars

Dr Priscilla Muheki[1], Dr Eike Guenther[2]

[1]Mbarara University of Science and Technology. [2]Thueringer Landessternwarte Tautenburg

Abstract

In the search for habitable exoplanets, it is important to consider the effects of energetic stellar events in the form of flares and Coronal Mass Ejections (CMEs) on potentially habitable planets. These phenomena can either lead to eroding off of planetary atmospheres or optimistically be a means of initiating prebiotic chemistry on planets. This is particularly important for planets orbiting M-stars, because these stars are very active and stay in this state for a long period of time. Here we present findings from the spectroscopic monitoring of two active M stars AD Leo and EV Lac. Using these data, the behaviour of the spectral lines Hα, Hβ, and He I 5876 was studied in detail and asymmetric features that might be Doppler signatures of CMEs investigated. Although several spectra showed asymmetries both in the blue and red, the velocities were much lower than the escape velocities of the stars. A possible erupting filament from a quiet region was also observed on EV Lac which largely suggests the great impact of the strong magnetic fields of these stars on preventing CMEs from escaping from the star. We will also briefly highlight on flaring as a function of age.

Hot Subdwarf stars in the integrated light of old stellar populations

Thayse Pacheco

Universidade de São Paulo/ Universidade Federal do Rio Grande do Sul

Abstract

Observational evidence indicates that hot Horizontal Branch stars are the most likely candidates to account for the ultraviolet excess of old globular clusters and elliptical galaxies. These hot and evolved components are still missing in most of the libraries used in the synthesis of stellar populations. Due to this, some differences between models based on resolved and integrated light spectral fitting can translate into age differences of up to 50% in low metallicity globular clusters.

To address this problem, we first computed a detailed grid of non-LTE fully line-blanketed stellar atmosphere models for hot and moderately cool Horizontal Branch stars. This new library also provides high-resolution spectra and synthetic photometry in the range from 1,000 – 10,000 Å.

Secondly, this library was combined with others in the literature to model the integrated spectra of simple stellar populations based on the color-magnitude diagrams of NGC 2808 and NGC 7089. We propose modifying the CMD-based methodology in literature by directly matching each observed star to a synthetic spectrum in a ten-dimensional color plane, avoiding inaccuracies of current color-Teff relations. This allows us to quantify the impact of Blue/Extreme Horizontal Branches in the integrated flux of the far ultraviolet. This impact has been shown to vary across the blue part of the spectrum, contributing up to 100% in the far-ultraviolet, but still showing significant contributions in the near-ultraviolet of around 20%. These models show remarkable agreement with observations over a very long baseline, from 1,200 to 6,300 Å.

Abstract

The mass of main-sequence stars plays an essential role in the determination of their evolution and interior structure. Main-sequence stars in the mass transition zone between convective and radiative cores offer an opportunity for testing the sensitivity of stellar core properties to the variations of stellar core physics, such as core overshoot, metallicity, atomic diffusion and gravitational settling. In this poster, we employ the Alpha Century binary as our benchmark star in the mass transition zone to unveil the impact of stellar model physics and different combination of observable constraints on the nature of stellar cores.

Multiple Peaks and a Long Precursor in the Type IIn Supernova 2021qqp

Dr. Daichi Hiramatsu

Center for Astrophysics | Harvard & Smithsonian

Abstract

Type IIn supernovae (SNe IIn) show narrow hydrogen emission lines due to the strong interaction between the SN ejecta and massive circumstellar material (CSM) from progenitor mass-loss activities. In this talk, I present optical photometry and spectroscopy of SN IIn 2021qqp. Its unique light curve is marked by a ~300-day-long precursor and two distinct sharp peaks respectively at -19.5 and -17.3 mag separated by ~335 days. The spectra are dominated by Balmer lines with a complex morphology, indicating the velocity evolution of the CSM from ~1300 km/s (first peak) to ~2500 km/s (second peak) and the SN—CSM interaction shell from ~8500 km/s (first peak) to ~5600 km/s (second peak). Using the bolometric light curve and velocity evolution, we construct a flexible analytical model, finding two significant mass-loss episodes with peak mass-loss rates of ~10 Msun/yr and ~5 Msun/yr about 0.8 and 2 years before explosion, respectively, with a total CSM mass of ~2–4 Msun. The SN ejecta mass is constrained to be ~5–30 Msun for an explosion energy of ~3–10e51 erg. Finally, I discuss eruptive massive stars (luminous blue variable, pulsational pair instability) and an extreme stellar merger with a compact object as possible progenitor channels of for generating the energetic explosion in the complex CSM environment.

Relativistic Magnetohydrodynamics for Amplification of Magnetic Fields during the Binary Neutron Stars Merger

Ms Magdeline Mohlao Seabi, Prof Azwinndini Muronga

Nelson Mandela University

Abstract

Binary neutron stars (BNSs) mergers are at the centre of observational targets for gravitational-wave detectors. BNSs mergers give insight into the state of hot dense matter generated under extreme conditions and also offer valuable information about the origins of heavy elements in the Universe and the formation of magnetars, etc. To understand the observations, solutions derived from general-relativistic equations are employed, to describe the dynamics of magnetic fields, and to further comprehend this phenomenon, a thorough investigation of relativistic magnetohydrodynamics (RMHD) studies is necessary. However, the equations within RMHD are highly non-linear and cannot be easily solved through analytical methods. The resolution of these equations requires numerical techniques within the framework of RMHD. To address substantial theoretical and technical challenges in discretizing RMHD equations, contemporary numerical relativity is employed to yield reliable results. Computational codes help model matter and magnetic field dynamics at pre-BNSs mergers to hundreds of milliseconds post-BNSs mergers. Our study focuses on relativistic magnetohydrodynamics simulations that explain the amplification of magnetic fields during the BNSs merger.

Magnetic field maps and accretion properties of the young star GM Aurigae

Dr Bonnie Zaire

Universidade Federal de Minas Gerais (UFMG)

Abstract

The study of young accreting stars has been crucial in advancing our understanding of planet formation, evolution, and habitability, as their circumstellar discs are believed to be natural birthplaces for planets. Playing a central role in these systems are magnetic fields, which mediate the star-disc interaction, control the accretion process, and regulate the exchange of mass and angular momentum between the star and its environment. This talk aims to study the magnetic field and magnetospheric accretion process operative in the 2 Myr old protoplanetary system GM Aurigae. We present three large-scale magnetic field maps reconstructed from September 2021 to January 2023 using high-resolution near-infrared spectropolarimetry from SPIRou at CFHT. These maps reveal a predominantly axisymmetric poloidal field configuration, which places GM Aurigae close to other stars with similar internal structures. A dipole of about 700 G dominates the field configuration, while higher-order harmonics account for less than 35 per cent of the total energy. The main difference between the magnetic maps is due to a magnetic field excursion, wherein the dipole field changes its meridional and azimuthal tilts. Finally, we constrain the ratio between the corotation radius and magnetospheric truncation radius of GM Aurigae to 1.7 ± 0.4, which places the star near the boundary between stable and unstable accretion regimes ($\sim$1.4). Nonetheless, we conclude that the star was likely in a stable accretion regime due to the periodic variability of the redshifted absorption reported for the near-infrared hydrogen emission lines.

Stellar Parameters on the Panchromatic Stellar Atlas (PaStA)

Morgan Camargo[1], Dr. Alessandro Ederoclite[2], Dr Ramachrisna Teixeira[1]

[1]Universidade de São Paulo. [2]Centro de Estudios de Física del Cosmos de Aragón

Abstract

Wide field surveys are powerful tools for astrophysical studies. These observations target a very large number of sources, building vast databases which can be used for studies which transcend the original goals of the projects. With the advance of technologies in the last decades, the storage and distribution of these databases have become much more accessible. The Sloan Digital Sky Survey and the Gaia mission are good examples of this change of paradigm.All surveys have strengths and weaknesses which are defined by their own primary science goals, like their limiting magnitudes or the wavelength coverage. For instance, Gaia focuses on optical light to derive position and velocities, whereas WISE only probes in infrared, and the GALEX All Sky Survey observed only the ultraviolet extragalactic sky.The Panchromatic Stellar Atlas (PaStA) has been developed to build up on the strengths of different surveys, joining these observations to create a database of stellar spectral energy distributions ranging from ultraviolet to infrared. Initially, we used PaStA to test stellar models and search for exotic objects. The Atlas is now evolving, there are now better corrections of interstellar extinction to be applied with recent publications, and with these important additions, we can further populate the catalogue with stellar atmospheric parameters for each object.

Photometric binaries in Magellanic Cloud star clusters

Ms. Anjana Mohandasan

University of Padova

Abstract

Binaries are fascinating objects that hold a fundamental and significant position in stellar evolution studies. Being a dense environment, Globular clusters (GCs) host a substantial amount of binaries, many of them being primordial. By studying the binary fraction in GCs, we can not only accurately determine the various cluster parameters, such as age, luminosity function, radius, and mass, but also understand the formation scenarios of its various stellar populations.

Extra Galactic GCs, like the ones in Magellanic Clouds (MCs), are quite interesting due to the wide ranges of ages and densities they span. Yet, they are less explored compared to their Galactic counterparts due to resolution limitations. In this study, we have successfully explored the MS binaries in 20 MC GCs using high-precision astrometry and photometry obtained from Space Telescopes. Thus derived binary fraction is investigated for its monovarietal relations with the main structural parameters of the clusters, including age, metallicity, mass, dynamical age, and density. The behaviour of binary fractions with stellar parameters, such as the mass of the primary star, the mass ratio between the companion stars, and radial distances yield interesting results. The comparison of results obtained from young and intermediate-age MC clusters, with those from old Milky Way GCs, opens a window into understanding the influence of cluster age and environment on stellar evolution and cluster dynamics. Additionally, it gives valuable insights into the relationship between binaries and exotic objects, such as Blue Straggler Stars, which are often present in the exciting expanses of GCs.

Stellar modelling with conformal symmetry

Dr Chevarra Hansraj, Prof Rituparno Goswami, Prof Sunil Maharaj

University of KwaZulu-Natal

Abstract

Solutions to Einstein's field equations (EFEs) are useful in describing compact stellar objects which have very strong gravitational fields and high densities. Different solutions depict different scenarios. For example, the Schwarzschild solution describes a compact stellar object with constant density in hydrostatic equilibrium. The Kerr solution describes a rotating uncharged axially symmetric black hole. Finding solutions to the EFEs is difficult in general because they are a system of complicated nonlinear partial differential equations. Ad hoc methods need to be employed to make them simpler to work with such as assuming a type of symmetry, for example, conformal symmetry. Pressure anisotropy is an important quantity which includes the difference in pressures that exist within relativistic bodies. Several situations occurring in stellar bodies can cause pressure anisotropy which influences the stability of stellar structures. We study the kinematical and dynamical properties of spacetimes that admit a conformal Killing vector (CKV) through spacetime decomposition. This provides new insights into the behaviour of physical quantities such as acceleration, expansion, shear and vorticity. The energy momentum tensor for an anisotropic fluid is decomposed which makes it possible to generate constraint equations that must be satisfied for a CKV to exist. We apply our results to the perfect fluid model and noteworthily we show that the conformal factor satisfies a damped wave equation. We further show that in the case of the pure null dust (or Vaidya) spacetime, a proper CKV cannot be admitted and briefly present the effects in rotating black hole geometry.

Optimisation of stellar pulsation modelling of BL Her stars using MESA-RSP

Dr. Susmita Das

CSFK Konkoly Observatory

Abstract

We present new theoretical period-luminosity (*PL*), period-Wesenheit (*PW*) and period-radius (*PR*) relations at multiple wavelengths (Johnson-Cousin-Glass bands *UBVRIJHKLL'M* and Gaia passbands $GG_{BP}G_{RP}$) for a fine grid of convective BL Herculis models computed using the non-linear radial stellar pulsation tool MESA-RSP. The non-linear models were computed for periods typical for BL Her stars, i.e. 1≤P (days)≤4 covering a wide range of input parameters: metallicity (-2.0 dex≤ [Fe/H]≤ 0.0 dex), stellar mass ($0.5M_{\odot}$-$0.8M_{\odot}$), luminosity ($50L_{\odot}$-$300L_{\odot}$) and effective temperature (full extent of the instability strip; in steps of 50K). We investigate the impact of four sets of different convection parameters on multi-wavelength properties. Most empirical relations match well with the theoretical *PL*, *PW* and *PR* relations from the BL Her models computed using the four sets of convection parameters. However, *PL* slopes of the models with radiative cooling provide a better match to empirical relations for BL Her stars in the LMC in the *G*-band and the HK_S bands. No significant metallicity effects are seen in the *PR* relations. Another important result from our grid of BL Her models is that it supports the equivalence of the *PL* relations of RR Lyrae and T2Cs, thereby providing us the opportunity of adopting RRLs+T2Cs together as an alternative to classical Cepheids for the extragalactic distance scale calibration.

An observational and theoretical view of the stellar photosphere-hydrogen ionization front interaction in classical pulsators

Dr. Susmita Das

CSFK Konkoly Observatory, Budapest

Abstract

The hydrodynamics of the outer envelope structure in classical pulsators can be studied using the period-colour relations at different pulsation phases. In this work, the hydrogen ionization front (HIF)-stellar photosphere interaction theory is probed from both the observational and theoretical aspects. Empirical period-colour (PC) relations for the classical pulsators exhibit flat/sloped PC relations for RRab stars at minimum/maximum light; sloped/flat PC results for W Vir stars and long-period (P >10d) classical Cepheids at min/max light and intermediate behaviour with a much smaller difference between the PC slopes at max/min light for BL Her stars and short-period (P < 10d) Cepheids. The theoretical aspect involves studying the HIF-stellar photosphere distances from stellar pulsation models computed using MESA-RSP. We found the results from the models to be generally consistent with this picture and thereby demonstrated that the theory holds true across a broad spectrum of variable stars in different evolutionary stages.

The LADUMA CV: Multiwavelength study on an SU-UMa Type Dwarf Nova in the LADUMA field using MeerLICHT and MeerKAT

Miss Sumari Barocci-Faul

University of Cape Town. South African Astronomical Observatory

Abstract

I will report on the optical-radio study of the outbursting cataclysmic variable star CRTS J033349.8-282244 in the LADUMA field. The source has extensively been observed with multiple South African and international facilities. I will present the results from observations of the CV done with MeerLICHT, MeerKAT and SAAO telescopes throughout outbursts, super-outbursts and during quiescence. The LADUMA field is frequently observed by the MeerKAT radio array as well as MeerLICHT, which observes the field in multiple filters. This resulted in a unique dataset to study the colour evolution of this CV, specifically a Dwarf Nova, as a function of the outburst phase for many dwarf nova outbursts - a study that has never conclusively been done before.

Spectroscopy of the HD68695 star using the Mahikeng Astronomical Telescope

Mr Lobone Nchoe

North-West University

Abstract

Through multi-wavelength observations, we anticipate strong infrared excess from HD 68695, these infrared excess are believed be caused by the presence of a proto-planetary disk as explained by Keller et al. (2019). The presence of this disk will mean that our candidate star according to Murphy et al. (2020) is a Herbig star. Studying these types of stars presents an opportunity to study planet formation as they form within proto-planetary disks. It should be noted however that that the presence of infrared excess does not squarely conclude the stellar type, as stated by Draper et al. (2015). Our study proposes to determine whether HD 68695 can be classified as a λ-Bootis star or Herbig Ae/Be star. We plan to achieve this by making spectroscopic observations of this star using the Mahikeng Astronomical Telescope attached to the eShel échelle spectrograph, as well as the HRS (High-Resolution Spectrograph) from the South African Large Telescope (see appendix), making a comparison between both data sets. This will allow us to perform an abundance analysis of this star. Based on the analysis we will determine if there is an under-abundance of iron peak elements, determine infrared excess using JHK (infrared excess filters) using existing observations of the star.

The tango of the rotation and pulsations in KIC7756853: a *Kepler* Hybrid δ Sct-γ Dor binary system

Dr. Anya Samadi-Ghadim

Max-Planck-Institut für Sonnensystemforschung, 37077 Göttingen, Germany

Abstract

Pulsating late A-F-type stars are characterized as intermediate to fast rotators. Kepler observations have revealed that due to their fast rotation γ Dor stars can have purely inertial and gravito-inertial pulsations. The advent of new-generation space missions, *Kepler* and TESS, has revealed hybrid stars exhibit pulsation frequencies falling within the range of 5-10 d^{-1}. KIC 7756853, a bright Kepler target of magnitude Kp = 8.96 mag, is a confirmed double-lined spectroscopic system following a comprehensive study based on high-resolution spectra. This system has an orbital period of 99.32 days, a mass ratio of 0.91, and consists of two A-type stars with projected rotational velocities = 31 and 51 km/s. From the Fourier analysis applied to the complete *Kepler* long-cadence data we detected δ Sct-type modes with frequencies ranging from 18.24 -28.28 d^{-1}. Two distinct regular frequency splittings were observed in both p and low-frequency modes, linking these pulsation modes to two of the most significant low frequencies, 0.8914 d^{-1} and 2.5258 d^{-1}. Significant low-frequency modes, indicative of inertial and gravito-inertial modes, were observed in the inertial (0.7 - 5.1 d^{-1}) and the super-inertial range (5.1 - 7. d^{-1}). The observed frequency splittings arise from the rotational effects of both primary and secondary components and allow us to deduce a core-to-surface rotation rate of 1.062 for the secondary. The coupling of rotation and pulsation in KIC 7756853 suggests the presence of a pair of (δ Sct – γ Dor) hybrid pulsators with intermediate to fast rotation.

Rotational period determination of selected chemically peculiar stars.

Caiyun Xia, prof. Zdeněk Mikulášek, Dr. Jan Janík

Masaryk University, Czech Republic

Abstract

About 10% of stars on the upper main sequence of HR diagram show anomaly abundance of some chemical element on their surface layers. The appearance of light curves of magnetic chemically peculiar stars are the same even for decades. This is due to a strong global magnetic field which leads to originating of spots on stellar surface and decreasing of stellar flux. By analysing of these light curves, we are able to determine their rotational periods with high precision. We will analyse light curves from TESS mission for selected stars and determine their period of rotation.

Binary Population Synthesis: a case for detailed binary models

Dr. Max Briel

University of Geneva

Abstract

Binary population synthesis (BPS) has emerged as a vital tool in astrophysics, particularly in the contexts of gravitational wave and supernova studies. Binary interactions lead to unique astrophysics objects, such as double compact object, novae, blue stragglers, and Type Ia supernovae, while complicating the already intricate landscape of single star evolution. BPS codes, often categorized into rapid and detailed codes, offer avenues for exploring uncertainties in interaction mechanisms and formation pathways of exotic objects.

While rapid BPS codes dominate due to computational efficiency, detailed BPS models provide unique insights into rare events despite their higher computational costs. This talk highlights two cases revealing distinctive binary evolution behaviors: the formation of binary black holes through stable mass transfer in the BPASS code, and the emergence of rapidly spinning gamma-ray burst progenitors via "reverse mass transfer" onto hydrogen-poor stars at high metallicity with POSYDON. Both these (semi-)detailed BPS codes provide an insight into these events due the usage of detailed stellar modelling. These examples underscore the essential role of detailed stellar physics, especially in understanding mass transfer stability and transients originating from binary populations.

Hour-to-Decade+ Variability in Young Stellar Objects

Lynne A. Hillenbrand

California Institute of Technology

Abstract

Young (1-10 Myr old) stars are ubiquitous variables, in both continuum and spectral lines, over a wide range of wavelengths. YSO activity is driven by a combination of stellar physics and accretion/outflow physics, all viewed through a complex circumstellar dust geometry. The diversity of variability behavior in YSOs has been illustrated by the plethora of time domain surveys covering various parts of the wavelength, duration, and cadence parameter space. Our ability to classify lightcurves has grown more sophisticated and our understanding of the underlying phenomena driving the various forms of variability has improved. The presentation will provide an overview of YSO variability behavior on short to long timescales, and from low to high amplitudes. Special attention will be paid to the dramatic accretion outbursts signalling transition from ``low-state" to ``high-state" accretion phases of varying extremity.

Recent observations of Supernova associated Gamma-Ray Burst

Prof. Xianggao Wang[1], Mr De-Feng Kong[1], Dr WeiKang Zheng[2], Prof. Enwei Liang[1], Prof. Alexei V. Filippenko[2]

[1]Guangxi University. [2]University of California, Berkeley

Abstract

We present recent observations of observations of supernova associated gamma-ray burst. Espically the GRB 221009A, in some respects the most extraordinary gamma-ray burst (GRB) ever observed. Good quality in the R-band light curve is obtained, covering 0.32--19.57 days since the Fermi-GBM trigger. We find that a weak bump emerges from the declining afterglow at about 11 days; a supernova (SN) may be responsible. We use a smooth broken power-law and Ni-56 model to fit the light curve. The best-fitting results reveal that the SN ejected a total mass of M_ej = 3.43 M_\odot$, a Ni-56 mass of M_Ni = 0.32 M_\odot$, and a kinetic energy of E_SN,K= 8.52 \times 10^{52} erg. We also compare GRB 221009A with other GRB-SN events based on a GRB-associated SN sample, and find that only SN 2003lw and SN 2011kl can be obviously revealed in the afterglow of GRB 221009A by setting these objects at its distance. This suggests that a supernova (SN 2022xiw) is possibly obscured by the brighter afterglow emission from GRB 221009A.

Asteroseismology vs Binarity: the battle for the old red stars

Dr Kelly Hambleton

Villanova University

Abstract

For main sequence stars, the asteroseismic scaling relations have been shown to provide stellar radii and masses to accuracies of 5% and 10%, respectively. For red giants, however, the discrepancy is more significant, on the order of 10% and 15%, attributed to the non-linearity of the scaling relations alongside the use of the Sun for calibration. Extensive attempts have been made to calibrate the asteroseismic scaling relations for red giants, including the analysis of pulsating red giants in eclipsing binary systems (RGEBs). Through the analysis of RGEBs, a direct comparison can be made between the scaling relation-derived masses and radii, and those derived through binary modeling. The premise of such work is that the results from modeling eclipsing binary system are ground truth and that the asteroseismic results should be adjusted accordingly. The catch is that binary star results are contingent on the treatment of the trends in the data and the application of an appropriate model, especially when the stars are non-spherical. Here we provide updated binary star masses and radii, determined using a state-of-the-art binary star modeling code (PHOEBE 2) for a selection of RGEBs. We highlight the importance of using a model with Roche geometry for distorted stars. Finally, we provide a comparison between the updated binary results and those from the asteroseismic scaling relations.

Abstract

Our nearest star-forming galaxy, the Large Magellanic Cloud (LMC), has been largely neglected in X-ray binary (XRB) populations studies targeting quiescent luminosities. In Chandra Cycle 24, we were awarded a Very Large Program (1 Ms) to perform a comprehensive survey of sources brighter than ~2 x 10^{32} erg/s in 10 LMC fields dominated by young (10 - 100 Myr) stellar populations of different ages, matching those sampled in the similar survey of the Small Magellanic Cloud (SMC). This luminosity limit probes all active XRBs and reaches into the regime of quiescent binaries and X-ray emitting normal stars. This program will provide the deepest X-ray luminosity functions (XLFs) for XRBs ever recorded, and in combination with the SMC survey will allow us to directly measure their formation efficiency as a function of age and metallicity and address the XLF evolution in the 10 - 100 Myr range. Here we present the first promising results from the analysis of the first 400 ks.

S-type and symbiotic Stars from LAMOST DR10: Classification and New Identifications

Dr Jing Chen[1,2], Prof A-Li Luo[2], Dr Yin-Bi Li[2], Dr Liang Wang[1], Dr Zi-Chong Zhang[1]

[1]Nanjing Institute of Astronomical Optics & Technology, Chinese Academy of Sciences.
[2]National Astronomical Observatories, Chinese Academy of Sciences

Abstract

S-type stars are cool giant stars with C/O ratios between 0.5 and 1.0. They have prominent ZrO molecular bands in their spectra and show an enrichment of s-process element. The largest catalog of S-type stars contained only slightly over one thousand stars, and there was no quantitative method to classify S-type stars suitable for large-scale photometric and spectroscopic surveys. We found 2939 S-type stars from LAMOST Data Release 10 using two machine-learning methods, and 2306 of them were reported for the first time. We divided S-type stars into intrinsic and extrinsic stars with photometric data and LAMOST spectra. Using infrared photometric data, the model trained by input features with 2MASS, AKARI, and IRAS data has the highest accuracy of 95.52%, and 381 intrinsic and 495 extrinsic stars were classified. Using these photometrically classified intrinsic and extrinsic stars, we retrained XGBoost model with medium-resolution spectra, and the 2939 stars were divided into 855 intrinsic and 2056 extrinsic stars with an accuracy of 94.82%. We also found four spectral regions of Zr I (6451.6 Å), Ne II (6539.6 Å), H alpha (6564.5 Å), and Fe I (6609.1 Å) & C I (6611.4 Å) are the most important features, which can reach an accuracy of 92.1% when using them to classify S-type stars. In addition, due to the possibility of symbiotic stars existing among the extrinsic S-type stars, we searched for symbiotic stars in the LAMOST spectra and found nine confirmed symbiotic stars, including two new discoveries.

New Data Release of AST3-2 Photometric Survey from Dome A, Antarctica

Dr Liang Wang, Dr Jing-Jian Chen, Dr Xiao-Yan Li, Prof Zheng-Yang Li, Dr Zi-Chong Zhang, Dr Jing Chen

Nanjing Institute of Astronomical Optics & Technology, Chinese Academy of Sciences

Abstract

Dome A in Antarctica has proved to be one of the best astronomical sites on Earth. Since 2012, a group of wide-angle 0.5m telescopes AST3 has been placed in Dome A to conduct a time-domain optical sky survey. One of its key programs has a sky field that largely overlaps with the southern continuous Viewing Zone (CVZ) of TESS. Zhang et al. (2018) analyzed the photometric data of 10 fields scanned in 2016, and found 179 new variables and 116 new transiting planet candidates. We developed new image calibration methods and applied them to the photometric data from all 32 fields from 2016 to 2017. We presented light curves of ~140,000 stars, of which 7,297 periodic variables have been listed in VSX or Gaia DR3 catalogs. We also identified 42 new variables and updated periods of some known variables. As these fields were observed before TESS, this dataset is particularly valuable for confirming the eclipsing binaries and exoplanet candidates identified by TESS and searching for TTV and ETV signals.

Search and study of young infrared stellar clusters

Naira Azatyan

Byurakan Astrophysical Observatory

Abstract

The Milky Way serves as a natural laboratory for astronomers, particularly for studying the origins and evolution of stars. The Galactic disc's "bricks" are giant molecular clouds, which are the birthplaces of stellar populations. Thus, there is a genetic connection between young stellar objects (YSOs) and their surrounding interstellar medium (ISM). Studying the ISM in conjunction with embedded YSOs is crucial for understanding the star formation process. This talk is dedicated to investigating star-forming regions, including determining the parameters of the ISM and YSOs. Among the 16 clusters we identified, we selected three star-forming regions for detailed study. It is likely that these three young stellar clusters were formed under different scenarios. The age spread of the IRAS05137+3919 and IRAS05168+3634 regions is much larger, leading us to conclude that their stellar populations formed as a result of independent condensations. In contrast, the age spread of the clusters' members in the third region, which comprises a pair of UCHIIs (G45.12+0.13 and G45.07+0.13), is small. We, therefore, concluded that their origin might be related to an external triggering shock. Moreover, high-mass YSOs were only found in the G45.07+0.13 and G45.12+0.13 UCHII regions, where the ISM's initial density was higher and star formation proceeded relatively quickly.

Buoyant crystals give a second life to white dwarf stars

Dr Antoine Bédard

University of Warwick (UK)

Abstract

White dwarfs represent the final stage of the life cycle of more than 95% of all stars. These stellar remnants are essentially devoid of energy sources and are thus condemned to cool continuously over billions of years — or so we thought. A few years ago, the Gaia mission uncovered a population of white dwarfs that have maintained a constant temperature for over 8 Gyr, revealing the existence of a powerful yet unknown energy source in these objects. This staggering challenge to conventional stellar physics prompted a flurry of modeling efforts aiming to identify the nature of the mysterious energy source. In this talk, I will show that the solution to this puzzle is the occurrence of a solid-liquid distillation mechanism triggered by the crystallization of the dense white dwarf core. For certain core compositions, the crystals forming at the center are depleted in heavy neutron-rich impurities, which makes them lighter than the surrounding liquid. The crystals float and eventually melt, causing heavier liquid to be gradually displaced downward, which releases a large amount of gravitational energy and thus interrupts the cooling for about 10 Gyr. This phenomenon had never been observed in any type of stars before and challenges our very notion of white dwarfs as dead stars. It also has profound implications for the use of white dwarfs in dating stellar populations and reconstructing the formation history of the Milky Way.

Abstract

Massive stars release vast amounts of energy into the interstellar medium through their lifetime processes and supernova explosions, compressing nearby regions and triggering star formation. While triggering mechanisms have been studied on smaller scales, comprehensive analysis on a larger Milky Way scale has been hindered by the lack of high-quality radio imaging and the limited angular resolution of molecular mapping. The significance of triggered star formation across the Galactic disc is, therefore, not well understood. Access to data from the MeerKAT Galactic Plane Survey and the Structure, excitation, and dynamics of the inner Galactic interstellar medium (SEDIGISM) molecular mapping survey addresses these limitations. This research combines MeerKAT and SEDIGISM data to identify molecular clouds interacting with HII regions and supernovae. The study examines differences between clouds interacting with Supernova Remnants (SNRs) and HII regions, analyzing any associated star formation. The anticipated outcome is the creation of a comprehensive catalog of clouds interacting with HII regions and SNRs. Comparing these clouds to the sample of non-interacting clouds aims to deepen our understanding of galactic-scale triggered star formation processes, and allow us to constrain the significance of its contribution to global star formation across galactic discs.

Gaps in the Main Sequence of Star Clusters with Gaia DR3 data

Dr Priya Shah

Maulana Azad National Urdu University, Hyderabad, India

Abstract

The presence of gaps or regions of small numbers of stars in the main sequence of the Hertzsprung Russell Diagram (HRD) of star clusters has been reported in literature. This is interesting and significant as it could be related to star formation and/or rapid evolution or instabilities. In this paper, using Gaia DR3 photometry and confirmed membership data, we explore the HRD of nine open clusters with reported gaps, identify them and assess their importance and spectral types.

Mass segregation in the Gaia Era

Dr Priya Shah, Prof Syed Najamul Hasan

Maulana Azad National Urdu University, Hyderabad, India

Abstract

In the present study, we used published membership data of 9 open star clusters as a training set to find new members from Gaia DR3 data using a supervised random forest model with a precision of around 90\%. The number of new members found is often double the published number.

We study mass segregation in a sample of clusters where mass segregaton has been reported. We find the mass function $\phi(M) = dN/dM \propto M^{-\alpha}$ in different regions of the clusters and tracing the variation in the value of α as a function of the parameter $\tau = t_{age}/t_{relax}$ (where t_{age} is the age of the cluster and t_{relax} is the relaxation time of the cluster). We explore relations of various parameters like Galactocentric distance, intracluster reddening (star formation efficiency (SFE)), age and size of the clusters to look for common defining features or signatures in them to help differentiate if the process is dynamical or related to their formation. Recent results supporting early dynamical mass segregation are discussed and attempts are made to critically assess the evidence of primordial mass segregation for the above sample.

From Collision to Creation: Origin of Hub-Filament Systems through Cloud-Cloud Collision

Mr. Arup Kumar Maity[1,2], Prof. Yasuo Fukui[3], Dr. Lokesh Dewangan[1]

[1]Physical Reserach Laboratory. [2]Indian Institute Of Technology Gandhinagar. [3]Nagoya University

Abstract

The massive star-forming regions (MSFRs) are commonly associated with hub-filament systems (HFSs) and the sites of cloud-cloud collision (CCC). Recent observational studies on Galactic MSFRs, such as SDC13, W31 complex, W33 complex, and AFGL 5180 & 6366S, have revealed concurrent signatures of CCC and the presence of HFS. This suggests that CCC may lead to the formation of HFSs. To understand the connection between CCC and the formation of HFSs, we conducted a comprehensive examination of magneto-hydrodynamic simulation data from Inoue et al. (2018), 70(SP2), S53 (1-11). This simulation involves the collision of molecular clouds at a relative velocity of ∼10 km/s with a spatial resolution of about 2400 AU. The supersonic collision between the cloud components develops a shock-compressed layer at their interface. The width and density of the shock-compressed layer increase over time. Following the collision, the turbulent and non-uniform cloud undergoes shock compression, resulting in the rapid development of filamentary structures within the compressed interface. Mass accumulation is facilitated along magnetic fields, promoting the development of heavier and denser filaments oriented perpendicular to the magnetic field. Finally, filaments converge toward a common junction under the influence of gravity to form a HFS, hosting a massive core of about 15 Solar mass at its hub. Overall, in the case of CCC, the combined influence of turbulence, shock compression, magnetic fields, and gravity contributes to the formation of HFSs and, subsequently, the birth of massive stars. During this presentation, I will share these research outcomes.

Exploring the complex nature of the intergalactic medium in Stephan's Quintet

Marina Arnaudova[1], Soumyadeep Das[1], Daniel Smith[1], Martin Hardcastle[1], Nina Hatch[2], Scott Trager[3]

[1]University of Hertfordshire. [2]University of Nottingham. [3]University of Groningen

Abstract

Galaxy mergers and interactions are a cornerstone of our understanding of how galaxies form, but their precise role in driving galaxy evolution across cosmic time is still widely debated. Compact galaxy groups at low-redshift, such as Stephan's Quintet (SQ), however, give us the opportunity to study such processes in more detail. This galaxy group is at a unique dynamical stage where we are able to observe manifestations of both past and present interactions by examining its most distinguished feature: the large-scale shock front. This system contains a wealth of multi-wavelength information including radio observations from the LOFAR Two-metre Sky Survey (LoTSS) and targeted observations with the Very Large Array (VLA). Recently, the next generation spectroscopic facility on the 4.2m William Herschel telescope in La Palma - WEAVE, has contributed to this wealth of information with its first panoramic optical integral field unit (LIFU) observation. By harnessing this instrument's large field of view and high spectral resolution (R=10 000), we are able to study the physical characteristics of the ionized gas by performing robust spectral fitting of complex line profiles on an individual spaxel of 2.6 arcsec basis across the area of 90x78 arcsec^2. This combined with radio spectral index maps (between 144MHz, 1.7GHz and 4.8GHz) allows us to determine the ionisation mechanism, age, and thermodynamics of the particles populating the structure, and thus shed new light on the interplay between galaxy-galaxy and galaxy-intergalactic-medium interactions.

[1]Space Telescope Science Institute. [2]University of Texas at Austin. [3]Universidade Cidade de Sao Paulo. [4]University of Geneva. [5]Astronomisches Rechen-Institut Heidelberg. [6]Universidad Nacional Autonoma de Mexico, Ensenada

Abstract

Star-forming galaxies are host to significant populations of recently formed hot, massive stars, which give rise to strong stellar spectral features in the ultraviolet and provide the ionizing fluxes of the stellar population. The properties of massive stars become more extreme at low metallicity and, thanks to pioneering observations of young, metal-poor stellar populations, both locally with HST and at high redshifts with JWST, we are at a key moment to assess our understanding of these galaxies through stellar population synthesis. This poster showcases the latest progress in extending the capabilities of the stellar population synthesis code Starburst99 to lower metallicities (covering a range from super-solar to zero metallicity) and higher upper mass limits (up to 500 solar masses). Thanks to the recent advent of new evolutionary and atmosphere models of massive stars in these extreme regions of the parameter space, we are able to characterize the integrated properties of such populations.

Interstellar dust in 3D at parsec-scale resolution out to 1.25 kiloparsecs in distance

Gordian Edenhofer

Max Planck Institute for Astrophysics. University of Munich

Abstract

Interstellar dust traces the mass in the ISM and is a crucial catalyst for star formation. To study the structure of the ISM and the conditions for star formation, we need to study the distribution of dust in 3D. However, we only observe interstellar dust in 2D projections. In this talk I will discuss how we can use astrometic data namely distance and extinction information from Gaia to de-project our 2D view of the sky to 3D. I will present a 3D map of interstellar dust extending out to 1.25 kiloparsecs in distance from the Sun. The 3D map improves upon previous high resolution 3D maps in terms of covered volume and resolution. It reveals previously undiscovered faint molecular clouds at high latitudes and far away distances, and significantly improves the dynamic range with which we resolve nearby molecular clouds.

The outskirts of M33: signatures of accretion or tidal interaction?

Dr. Edvige Corbelli

INAF- Osservatorio di Astrofisico di Arcetri

Abstract

By examining a variety of orbital initial conditions compatible with the Early Third Data Release of the Gaia mission and with mass estimates of Local Group spirals, we study the probability and the effects of a close pericenter passage of M33 around M31 in the past. A close encounter of M33 and M31 in the past has a low but non negligible probability. If the two galaxies had been closer in the past, their minimum distance was of the order of 100~kpc or larger, and this happened earlier than 3~Gyr ago. During this encounter 35-40% of the dark matter mass of M33 might have been removed from the halo due to tidal stripping. A detailed comparison of the results of test-particle simulations with the observed disk warp or with the spatial distribution of candidate dark satellites of M33 suggests that a closer passage of M33 around M31 cannot however be responsible for the observed morphological features. We suggest that more recent gas accretion events, possibly from a cosmic filament, might cause the misalignment of the outer disk of M33 after the rapid inner disk formation.

Experimental evidence of high temperature formation of H_2 and solid water on PAH-like surfaces

Mr Francesco Grieco

Ghent University (Belgium). LERMA laboratory (CYU, France)

Abstract

H2 is the cooling agent regulating star-formation and it requires dust grains as catalysts to be formed. PAHs have been shown to increase the H2 formation rate, believed to be very efficient only below 20 K and becoming irrelevant above 100 K. Water represents instead the main component of the icy mantles on dust grains and its solid-phase formation route is essential to explain abundances in molecular clouds.

We report direct experimental QMS results through the interaction of hydrogen and (for water) oxygen atomic beams aimed towards the surface, connected to a cryostat, and analyzed with temperature desorption techniques.

H2 is efficiently formed through atomic recombination on coronene, PAH-like surface, up to 250 K while solid water is obtained up to 85 K, mimicking the conditions from dense to translucent regions where the ice mantle onset starts.

Our experimental results could have important implications for the location of the H/H2 photodissociation front and for the formation of H2 in high-redshift galaxies where dust temperatures are generally above 40 K. Icy mantles could form in less dense and warmer environments, explaining oxygen depletion in the ISM and the disappearance of PAHs in translucent regions.

Correctly accounting for H2 formation is key for its line emission in local PDRs and for JWST observations of PAHs that, if combined with H2O observations, could further support the warm temperature solid water formation on those surfaces. Both these experimental works show the catalytic nature of coronene and the role of chemisorption processes. [1, 2]

[3]Centre for Astrophysics and Supercomputing, Swinburne University of Technology, Melbourne, Australia. [4]Many

Abstract

Starbursts are a rare phenomenon in the present day universe, but they represent the most common mode under which stars formed and galaxies grew during the z~1-2 peak of cosmic star formation activity. This mode of star formation is not a simple scaling of what happens in typical molecular clouds, but represents a much more efficient manner of converting gas into stars likely through the formation of massive clusters. The resulting feedback in the form of galaxy-scale outflows is, together with AGN, thought to be one of the main forms of regulation of galaxy growth. I will present recent imaging and spectroscopic JWST observations of two of the nearest starbursts, M 82 and NGC 253, and discuss the inferred properties of these starbursts and their dusty winds with particular emphasis on the feedback effects on the interstellar medium of these nearby galaxies. These images reveal the structure of the dust in the outflow on scales of a few parsecs, while the spectroscopy provides unique insights into the clusters at the extremely obscured core of the starburst.

Affordable Multiple Aperture Spectroscopy Explorer

Dr. Sabyasachi Chattopadhyay

South African Astronomical Observatory

Abstract

Affordable Multiple Aperture Spectroscopy Explorer (AMASE) is an optical spectroscopic survey of the ionized gas in Milky Way and all Local Group star-forming galaxies at spatial scales of 0.1 to 100 pc and a spectral resolution of σ = 8.5 km s^-1. Key emission lines captured include Hα, Hβ, HeII, and strong emission lines of forbidden OI, OIII, NII, and SII in two windows between 4640-5092 Å and 6250-6850 Å. These data will be used to uncover the process driving outflows in star-forming regions, to calibrate the metallicity measurements and photoionization models, and to understand the origin of the diffuse ionized gas. AMASE will pair many identical multi-fibre spectrographs with an array of telephoto lenses to achieve integral field spectroscopy at half-arcminute resolution over large areas of the sky. This is enabled by a significant reduction in the cost of each spectrograph relative to typical astronomical spectrographs of comparable performance. Cost-reduction is achieved by fibre-coupling and reducing the beam size to match commercial photographic lenses and large-format, small-pixel CMOS detectors. High performance is achieved by recent advances in detectors, optical coatings and new grating technology (fused-silica etched gratings that outperform even volume phase holographic gratings). In this talk the speaker will discuss the scientific motivation and update on the instrument development progress.

LightCube: A 3D Model of the Local UV Interstellar Radiation Field

Dr. Hannah Bish[1], Dr. Joshua Peek[1,2], Dr. Claire Murray[1], Dr. Karl Gordon[1], Dr. Catherine Zucker[3]

[1]Space Telescope Science Institute. [2]Johns Hopkins University. [3]Harvard-Smithsonian Center for Astrophysics

Abstract

Traditionally, studies of the Milky Way and ISM have assumed a constant value for the interstellar radiation field (ISRF) in the nearby Galaxy. This is often the most reasonable assumption given the limited information we have. In reality, the ISRF varies depending on proximity to stars, dust extinction, and other factors, and these variations can greatly influence the properties of diffuse matter. Thanks to recent progress in the quality of local dust maps and distances to UV-bright stars, we are now able to calculate a detailed representation of the UV radiation background within 370 pc of the Sun - a data set we call LightCube. We present this data set, discuss our initial findings, and touch on potential uses of LightCube by the community.

New Observations of the Fermi Bubbles: Tracing Nuclear Feedback and in-situ Conditions

Dhanesh Krishnarao

Colorado College

Abstract

The biconical gamma-ray lobes known as the Fermi Bubbles likely trace nuclear feedback and winds from the Galactic Center. These winds have been observed in several wavelengths, ranging from radio to UV to trace individual clouds outflowing from the CMZ region at large scales. These studies however have been limited to small regions near the galactic plane to find cold gas, or rely heavily on background quasars for UV absorption line studies for a bigger picture. Now, we have directly observed this outflowing gas using recombination line emission in the optical and radio wavelengths, providing a more holistic picture into the feedback effects and radiation field emerging from Galactic Center at large scales. Our discovery (Krishnarao et al. 2020a, ApJL; Krishnarao et al. 2020b, Science Advances) provides in-situ measurements of ionized gas density, temperature, and pressure, suggesting that the Fermi Bubbles may be creating an over-pressured zone of ionized gas within a few kpc of Galactic Center. The combination of optical/radio recombination line emission and UV absorption from the same Fermi Bubble gas allows us to directly constrain the escaping radiation field from the Galactic Center environment and indirectly model the underlying stellar population and distribution (Krishnarao, Cashman, & Fox. 2022, HST AR 17060). Soon, using the Wisconsin H-Alpha Mapper and Green Bank Telescope, we will be able to create the first, continuous, 4-Dimensional (position + velocity) maps of the Fermi Bubbles via emission lines.

Peering into the MilkyWay by FAST: I. Exquisite HI structures in the inner Galactic disk from the piggyback line observations of the FAST GPPS survey

Dr. Tao Hong, Prof. Jinlin Han, Dr. Ligang Hou

National Astronomical Observatories, Chinese Academy of Sciences

Abstract

Neutral hydrogen (HI) is the fundamental component of the interstellar medium. The Galactic Plane Pulsar Snapshot (GPPS) survey is designed for hunting pulsars by using the Five-hundred-meter Aperture Spherical radio Telescope (FAST) from the visible Galactic plane within $|b| \leq 10°$. The survey observations are conducted with the L-band 19-beam receivers in the frequency range of 1.0-1.5 GHz, and each pointing has an integration time of 5 min. The piggyback spectral data simultaneously recorded during the FAST GPPS survey are great resources for studies on the Galactic HI distribution and ionized gas. We process the piggyback HI data of the FAST GPPS survey in the region of $33° \leq l \leq 55°$ and $|b| \leq 2°$. The rms of the data cube is found to be approximately 40 mK at a velocity resolution of 0.1 km s^{-1}, placing it the most sensitive observations of the Galactic HI by far. The high velocity resolution and high sensitivity of the FAST GPPS HI data enable us to detect weak exquisite HI structures in the interstellar medium. HI absorption line with great details can be obtained against bright continuum sources.

Asteroseismic ages for the development of chemical age determination methods

Prof. Grazina Tautvaisiene, Dr. Erika Pakstiene, Dr. Yuriy Chorniy, Dr. Carlos Viscasillas Vazquez, Dr. Arnas Drazdauskas, Dr. Sarunas Mikolaitis, Dr. Renata Minkeviciute, Dr. Edita Stonkute, Mr. Vilius Bagdonas, Dr. Carlos Viscasillas Vazquez

Vilnius University

Abstract

For the deeper understanding of the Galactic chemical evolution, three main parameters of stars have to be known – the detailed chemical composition, age, and the birth place. So far the stellar age determination has largest uncertainties. In this work, we use a unique opportunity to use the TESS Space Mission data for the asteroseismic age determination, the Gaia Space Mission data for more precise stellar birth-place determinations, and a detailed chemical composition of bright stars located in the northern TESS continuous viewing zone and 12 degrees around it. Among all stars of $V < 8$ mag, we found 238 stars with clear solar-type pulsations and determined their asteroseismic ages. This allowed to compare the isochronal and asteroseismic age determinations. Using [C/N] and [Y/Mg] abundance ratios, we also addressed the emerging chemical-clock method applicability for stars of the thin and thick discs in different Galactic radial distances.

Overview of the ALMA Large Project FAUST

Dr. Yoko Oya[1], Dr. Cecilia Ceccarelli[2], Dr. Clare Chandler[3], Dr. Claudio Codella[4], Dr. Nami Sakai[5], Dr. Satoshi Yamamoto[6]

[1]Center for Gravitational Physics and Quantum Information, Yukawa Institute for Theoretical Physics, Kyoto University, Kyoto, 606-8502, Japan. [2]Universite Grenoble Alpes, CNRS, IPAG, France. [3]National Radio Astronomy Observatory, United States. [4]INAF, Osservatorio Astrofisico di Arcetri, Italy. [5]RIKEN, Japan. [6]SOKENDAI, Japan

Abstract

It has been recognized that protostellar cores show chemical diversity, especially in the composition of organic species. For instance, two distinct cases are well known; hot corino sources are rich in interstellar complex organic molecules, while warm carbon-chain chemistry sources are rich in unsaturated hydrocarbons. They are still unclear whether such a chemical diversity is seen in disk-forming regions and what kinds of molecular species are delivered into disks from envelope gas.
To tackle with the above problems, our ALMA large program 'FAUST (Fifty AU STudy of the chemistry in the disk/envelope system of Solar-like protostars)' focuses on the early stage of Solar-type protostars and their chemical diversity on a 50 au scale, where a planetary system is expected to be formed. The main goal of this project is to quantify molecular abundances of the disk/envelope system in relation to its physical structure and to reveal how different they are among sources. For this purpose, we observed thirteen young protostellar sources as representatives of the chemical diversity observed on larger scales to obtain a homogeneous database of thousands of images from different lines and species. The analysis of this huge database is in progress to disentangle the components of the 50-2000 au disk/envelope system, to characterize the organic complexity in each source, to delineate their distribution, and to probe their ionization structure. In this presentation, we especially focus on the chemical diversity among sources and the differences of the molecular distributions.

Testing the Supermassive Star Scenario for Early Massive Cluster Evolution

Katarzyna Nowak

University of Hertfordshire

Abstract

For a long time, it was believed that globular clusters were simple structures consisting of only one population of stars that share the same chemical composition. However, recent extensive evidence shows that these old and massive stellar aggregates exhibit significant differences in lighter elements with the Na-O anticorrelation being the most prominent feature in most of them. Additionally, multiple sequences in the colour-magnitude diagram suggest a spread in helium abundance in most Galactic and extra-galactic globular clusters. The most likely explanation for the chemical peculiarities observed in globular cluster is self-enrichment, where specific stars pollute the surrounding gas with their yields. Supermassive stars (> 1000 Msun) are proposed candidates for polluters but at the present time it is very hard to observe them due to their location. The candidates forming massive clusters are located outside the Milky Way with very dense centers, where the hypothetical star would be obscured by gas and dust. The supermassive stars would form via runaway collisions, simultaneously with the cluster, hence their disc is perturbed by stellar flybys.

We use a 3D hydrodynamic simulations set up around a supermassive star to examine how its accretion disc reacts to frequent stellar encounters. We examine if the disc survives and remains dense enough to mase water lines. We then model kilomasers, which are generally associated with the forming super star cluster and compare it to an interesting candidate in the starburst galaxy NGC 253.

Investigating Self-Enrichment in Young Massive Clusters through ^{26}Al Signatures

Katarzyna Nowak

University of Hertfordshire

Abstract

Self-enrichment is one of the leading explanations for chemical anomalies in globular clusters. In this scenario, a certain polluter star, enriches a forming cluster with its yields, likely ejecting radioactive 26Al into its surroundings. Detection of 26Al in young massive star clusters holds significant implications, potentially supporting the self-enrichment scenario if these clusters are indeed progenitors of globular clusters. Recent advancements in observational techniques, including detections of the 1.8 MeV and 511 keV 26Al decay gamma ray lines, as well as 26AlF molecules or positronium radio recombination lines, suggest promising avenues for detecting 26Al and maturing detection methods.

In this talk, I will focus on examining a sample of young massive star clusters in the nearby Universe, where self-enrichment could plausibly occur. Despite optimistic scenarios, detecting most sources remains challenging with some methods. However, we identify R136 in the Large Magellanic Cloud as a promising candidate for such investigations. Although the best-case scenario for detecting a 1.8 MeV signal may require several years with instruments like COSI, the feasibility of detecting 26AlF with the ALMA telescope in several candidate clusters offers encouraging prospects for further study and understanding of self-enrichment scenario in young massive star clusters.

The Ratio of $^{12}C_2$ and $^{12}C^{13}C$ Column Densities in Diffuse Molecular Gas

Steven Federman[1], Adam Ritchey[1], Evelyne Roueff[2], Jacques Le Bourlot[2], David Lambert[3], Joe Ninan[4], Suvrath Mahadevan[5], Gregory Zeimann[3], Steven Janowiecki[3]

[1]University of Toledo. [2]Observatoire de Paris. [3]University of Texas at Austin. [4]Tata Institute of Fundamental Research. [5]The Pennsylvania State University

Abstract

We describe a study yielding the $N(^{12}C_2)/N(^{12}C^{13}C)$ ratio with the Habitable-zone Planetary Finder (spectral resolution of 6 km s^{-1} and signal-to-noise per resolution element from 900 to 2000) on the Hobby-Eberly Telescope (HET) in West Texas. The sample comprises sight lines toward stars that are accessible to HET and have $^{12}C_2$ column densities greater than $7x10^{13}$ cm^{-2} in three or fewer velocity components. The focus is on absorption from the (1-0) band of the Phillips system ($A^1\Pi_u - X^1\Sigma_g^+$) near 1 micron toward the stars HD 28975, HD 29647, HD 169754, Cyg OB2 12, and HD 204827. These data are supplemented by results on the $N(^{12}CO)/N(^{13}CO)$ and $N(^{12}CN)/N(^{13}CN)$ ratios from absorption at infrared, visible, and ultraviolet wavelengths and radio emission. Q- and R-branch lines of $^{12}C^{13}C$ from J" = 0 to 3 are detected in all the stellar spectra except for HD 29647. Our findings to date reveal a $N(^{12}C_2)/N(^{12}C^{13}C)$ ratio of about 30, or an ambient $^{12}C/^{13}C$ ratio of ~60; such a value is consistent with expectations. However, toward HD 29647, only a lower limit for the $N(^{12}C_2)/N(^{12}C^{13}C)$ ratio of 100, or an ambient $^{12}C/^{13}C$ ratio greater than 200, is inferred. We are constructing models of chemical fractionation to interpret the range of column density ratios. Comparisons between observational results and model predictions will be presented.

Spectral Mapping of Nearby Galaxies Utilizing Multi-wavelength Data and Machine Learning Algorithms

Dr. Ji Hoon Kim[1], Prof. Myungshin Im[1,2]

[1]Astronomy Research Center, Seoul National University. [2]Department of Physics and Astronomy, Seoul National University

Abstract

Spectral mapping of nearby galaxies provides immense information into their physical properties, encompassing stellar populations, chemical composition, dynamical characteristics, and more. While recent surveys like SAURON, MANGA, and SAMI have advanced the field using integrated-field units (IFUs), these surveys are limited in sample sizes due to the expensive nature of IFU observations. In this presentation, we are introducing a pilot study utilizing the commissioning data of the 7-Dimensional Telescope (7DT), a multi-telescope array of 20 50-cm telescopes with 40 medium-band filters of 25 nm FWHM, which will ultimately provide spectral cubes of a large number of nearby galaxies in the southern hemisphere in conjunction with SPHEREx. While operating in different platforms and wavelengths - ground-based and optical for 7DT and space-based and near-infrared for SPHREx - both facilities provide comparable data in terms of spectral resolutions and survey depths. Combining data from these facilities, we can generate spectral cubes for nearby galaxies spanning the wavelength range from 400nm to 50000nm. In our pilot study, we plan to train a deep learning (DL) algorithm on low-resolution spectra observed by 7DT and high-resolution spectra obtained by VLT-MUSE of nearby galaxies selected from the PHANGS survey to examine if the DL algorithm recovers high-resolution spectra. If successful, we will apply the algorithm to the Wide-Field Survey, one of 3 layers of the 7-Dimensional Sky Survey, and expand the method for SPHEREx and PHANGS-JWST. The synergy between 7DS and SPHEREx can provide a comprehensive dataset as a valuable legacy resource for prospective studies of nearby galaxies.

Feedback and galaxy dynamics: A study of turbulence and star formation in 34 galaxies using the PHANGS survey

Dr. Bruce Elmegreen

NA

Abstract

To understand the effects of star formation feedback on ISM turbulence and future star formation, the relationship between molecular gas turbulent speed, sigma, and local star formation rate surface density, Sigma_SFR, is studied using CO observations of 17 strong-arm spiral galaxies and 17 weak-arm spiral galaxies in the PHANGS survey. Azimuthal fluctuations in sigma and Sigma_SFR correlate well, but apparently not because of feedback, because sigma depends on molecular surface density and cloud mass with the usual molecular cloud correlations, while Sigma_SFR increases with both of these quantities because of a nearly constant star formation efficiency per CO. Azimuthal variations of molecular pressure have a weaker correlation with Sigma_SFR than expected from the power-law correlation between these total quantities, suggesting slightly enhanced SFR efficiency per molecule in spiral arms. Dynamical equilibrium pressure, P_DE, and Sigma_SFR correlate well for the whole sample, both in total and with azimuthal fluctuations. Because of this close association even with young star formation, and because of the similarity between the components of P_DE and the Kennicutt-Schmidt and Extended KS laws, we suggest that P_DE should be viewed as both a precursor to star formation through its dependence on gas content and as a reaction to star formation through non-local feedback effects. Galactic dynamical processes are also studied. They all correlate well with Sigma_SFR, such that Sigma_SFR~(Sigma_gas x R)^{1.0+-0.3} for total gas surface density, Sigma_gas, and galactic dynamical rates, R, equal to either epicyclic frequency, shear rate, or orbital rate.

X-rays from a Central "Exhaust Vent" of the Galactic Center Chimney

Scott Mackey[1,2], Mark Morris[2]

[1]University of Chicago. [2]University of California, Los Angeles

Abstract

Using deep archival observations from the Chandra X-ray Observatory, we present an analysis of linear X-ray-emitting features located within the southern portion of the Galactic center chimney, and oriented orthogonal to the Galactic plane, centered at coordinates l = 0.08 deg, b = −1.42 deg. The surface brightness and hardness ratio patterns are suggestive of a cylindrical morphology which may have been produced by a plasma outflow channel extending from the Galactic center. Our fits of the feature's spectra favor a complex two-component model consisting of thermal and recombining plasma components, possibly a sign of shock compression or heating of the interstellar medium by outflowing material. Assuming a recombining plasma scenario, we further estimate the cooling timescale of this plasma to be on the order of a few hundred to thousands of years, leading us to speculate that a sequence of accretion events onto the Galactic Black Hole may be a plausible quasi-continuous energy source to sustain the observed morphology.

Properties and structure of the local ISM obtained from HST ultraviolet spectra as prototypes for the Galactic ISM

Prof. Jeffrey Linsky[1], Prof. Seth Redfield[2]

[1]University of Colorado at Boulder. [2]Depoartment of Astronomy Wesleyan University

Abstract

High-resolution spectra obtained with the STIS instrument on the Hubble Space Telescope are providing line widths and velocities that characterize interstellar gas in the sightlines to several hundred stars located within 100 pc of the Sun. All of these sightlines show at least one interstellar velocity component with partially ionized hydrogen, and many sightlines show multiple velocity components. Line widths for elements with different masses permit the separation of thermal from non-thermal (turbulent) components. The identification of different velocity components that share a comment velocity vector allowed the identification of 15 individual clouds located within about 10 pc of the Sun. The Sun appears to be located in a mixed cloud region where the Local Interstellar Cloud and the G Cloud overlap. Within 4 pc of the Sun, the local ISM is completely filled with partially ionized warm gas clouds, but with increasing distance, the clouds become isolated and are surrounded by fully ionized hydrogen produced by supernovae explosions. The temperatures and densities of the partially ionized gas in the local clouds are very inhomogeneous on small distance scales. There appears to be total pressure balance between the heliosphere, the local warm clouds, and the surrounding Local Cavity (Bubble) with ram pressure playing an important role. There are several proposed explanations for the structure of the local ISM.

Mixed aromatic/aliphatic organic nanoparticles as possible carriers of the unidentified infrared emission bands

Prof. Sun Kwok[1,2], Dr. SeyedAbdolreza Sadjadi[2]

[1]University of British Columbia. [2]University of Hong Kong

Abstract

Circumstellar envelopes of evolved stars are prolific sites of molecular synthesis. Starting with acetylene, aromatic molecules such as benzene can form. Aliphatic side chains have been observed to form around islands of aromatic rings, leading to complex mixed aromatic/aliphatic organic nanoparticles (MAONs). From quantum chemistry calculations, we show that MAONs have spectral properties similar of the family of identified infrared emission (UIE) bands widely observed in the interstellar medium. Comparisons will be made with other models of possible carriers of the UIE bands.

Characterising GRAO observations of 6.7-GHz methanol masers

Mr Stephen Sottie[1,2], Dr Emmanuel Proven-Adzri[2], Dr Theophilus Ansah-Narh[2]

[1]University of Ghana. [2]Ghana Space Science and Technology Institute, Ghana Atomic Energy Commission

Abstract

We developed a computational model that estimates the parameters that characterize GRAO masers. Three probability distribution functions (models), including Gaussian, Lorentzian, and Voigt models, were fitted onto the Maser data using Bayesian inference and Markov Chain Monte Carlo approaches. This estimated the fwhm, which determined the peak flux and central velocity of the Maser. For this work, the parameters for four Masers species (G9.62+0.20, G351.44+00.65, G328.277-00.530, and G339.884+1.259) were found. The Gaussian model fit for G9.62 + 0.20 (for instance) estimated the peak flux, central velocity, and FWHM values to be 998.920 Jy, 0.034 km/s, and 0.00079 km/s respectively. The Voigt model fits G339.
This tool does not only streamlines data analysis but also significantly contributes to astrophysical research in Ghana.

[11]Dunlap Institute for Astronomy & Astrophysics, University of Toronto. [12]The Observatories of the Carnegie Institution for Science

Abstract

The Large Magellanic Cloud (LMC) is the most massive Milky Way satellite dwarf galaxy and is thought to have only recently (~2 Gyr ago) fallen into the Milky Way. This recent infall means that the LMC's lowest metallicity stars ([Fe/H] < -2.5) provide a unique opportunity to study chemical evolution and element production by the first stars in a formerly distant, extragalactic environment. We present the detection and detailed chemical abundances of 10 stars between -4.2 < [Fe/H] < -2.5 in the LMC, the lowest metallicity of which is significantly more metal-poor than any prior LMC star with detailed chemical abundances. This star, with [Fe/H] = -4.13, is the most metal-poor star known in any external galaxy, and is at sufficiently low metallicity to plausibly reflect enrichment from an individual supernova from an extragalactic first star. Intriguingly, this star is not a carbon-enhanced metal-poor star (CEMP; with [C/Fe] > 0.7), in contrast to the lowest metallicity Milky Way halo stars where ~90% of stars with [Fe/H] < -4.0 are classified as CEMP. This lack of carbon-enhancement is also seen in the rest of our low metallicity sample, in addition to several other trends that suggest that the early LMC may have experienced diverging enrichment processes from the early Milky Way. These results, along with other recent studies, demonstrate that the very lowest metallicity stars are detectable in the LMC, opening up possibilities for testing the universality of early enrichment and the properties of the first stars in diverse cosmic environments.

Unveiling the Dynamics of Open Clusters: Insights from External and Internal Perspectives.

Dr. Carlos Viscasillas Vázquez

Vilnius University

Abstract

Delving into the dynamical evolution of open clusters offers invaluable insights into Galactic disc properties. Leveraging Gaia DR3 data, our study explores the temporal evolution of kinematical and dynamical characteristics within the Galactic open cluster population. Our investigation adopts a dual approach, scrutinizing both external perturbations and internal kinematic evolution. Externally, we investigate the determinants of cluster survival, including factors such as mass, density, size, and galactic perturbations. Internally, we employ diverse metrics to track the evolution of intra-cluster member distances over time.
This poster presentation unveils the boundaries and potential of the oldest open clusters as crucial tools for deciphering the complexities of our Milky Way.

Understanding circumnuclear environments in M31 and M81 with multi-wavelength, high-resolution observations

Dr. Zongnan Li

National Astronomical Observatories, Chinese Academy of Sciences

Abstract

Galactic circumnuclear regions, where stars and supermassive black holes interact with the interstellar medium, are crucial for understanding black hole feeding, feedback, and galaxy co-evolution. However, the connection between black hole feedback and the surrounding interstellar medium remains elusive. We utilizes multiwavelength observations of nearby galaxies (M31 and M81) to investigate the interaction between the multiphase interstellar medium and supermassive black holes in circumnuclear regions. Millimeter and infrared observations reveal a deficiency of cold gas in the circumnuclear region of M31 compared to the Milky Way, but with higher temperatures possibly linked to past nuclear activity. Additionally, optical spectroscopic observations uncover a biconical ionized gas outflow structure located at around 200 pc from the center of M81, likely associated with the low luminosity active galactic nucleus. We also addresses the long-standing puzzle of the origin of low-ionization nuclear emission-line regions (LINERs) in both galaxies. Using the CLOUDY photoionization code, the model incorporating contributions from inactive nuclei and stellar populations fails to fully explain the observed radial distribution of emission-line intensity within 1 kpc. This discrepancy suggests the presence of additional mechanisms, such as shocks or previous nuclear activity, in the ionization processes of these nearest LINERs.

MAUVE: Tracking the influence of the environment on the gas-star formation cycle of cluster galaxies during infall

Luca Cortese, Barbara Catinella

ICRAR-UWA

Abstract

I will present the first results from the MAUVE (MUSE and ALMA Unveiling the Virgo Environment) survey a multi-wavelength observational campaign combining VLT/MUSE, ALMA and HI observations of 40 galaxies in the Virgo cluster aimed at understanding the environmental impacts on the gas-star formation cycle in cluster galaxies during their infall. These data are allowing us to probe the distributions and kinematics of stars, ionized and molecular gas over the full extent of the inner galactic disks, at scales of a few hundred of parsecs, making it possible to investigate the link between cold gas and star formation when and where environmental processes are at play. Excitingly, these observations are starting to reveal unexpected cases of star formation driven outflows even in ram-pressure stripped and HI deficient galaxies, as well as providing new insights into how star formation proceeds after first pericentre passage. While still at the early stages, MAUVE is showing us how outflows may still play an important role in the full quenching of the star formation of satellite galaxies and highlight how a multi-phase mapping of the interstellar medium is critical to fully unveil the physical processes regulating the star formation cycle of galaxies.

Investigating the blue stellar clumps of the collisional ring galaxy Arp 142

Ms Lisa Seconna

University of Cape Town (UCT). South African Astronomical Observatory (SAAO)

Abstract

Star formation (SF) is a complex and dynamic process influenced by various factors including stellar feedback, gas dynamics, and environmental conditions. Formed through the head-on collision between a small galaxy companion and the rotation axis of a larger disk galaxy, collisional ring galaxies (CRGs) offer a unique laboratory that helps understand the origin of SF in clumpy systems. The collision is so intense that it triggers new episodes of starburst activities leading to the formation of blue stellar clumps. These objects represent the youngest and most massive (> 10^5 $M_\odot$) form of SF in nearby galaxies. In this work, we study a large sample of blue stellar clumps in the CRG Arp 142 using high-resolution HST multiband observations (PSF ~ 0.1''). By studying the photometric and physical properties of the stellar clump population, we aim to investigate the effects of the host environment on the cluster formation and evolution mechanisms. We find that clumps have approximate mass and age ranges of ~ 10^5 – 10^7 $M_\odot$ and ~ 10 – 500 Myr, respectively. Their spatial distribution suggests that their physical properties are likely influenced by the host environment.

The oldest stars in the Large Magellanic Cloud

Thomas Nordlander

Research School of Astronomy and Astrophysics, Australian National University

Abstract

The most metal-poor stars alive today carry the chemical fingerprints of ancient stars and supernovae. I will present a resent spectroscopic survey of metal-poor stars in the Large Magellanic Cloud that has uncovered seven of the most metal-poor stars known. Two of the stars are strongly r-process enhanced, with abundances matching the universal r-process pattern. The other five stars are not r-process enhanced, and therefore likely formed before the enhancement event (binary neutron star merger?) discovered by Reggiani et al. 2021, therefore clearly making them both the most metal-poor and oldest stars in this galaxy.

Properties of molecular clumps in the nearby galaxy: M33

Dr Saul Paul Phiri[1,2], Dr Jason Kirk[2], Prof. Derek Ward-Thompson[2], Dr Anne E. Sansom[2], Dr George Bendo[3]

[1]Copperbelt University. [2]University of Central Lancashire. [3]University of Manchester

Abstract

Resolving molecular clouds in external galaxies offers an opportunity to study the properties of molecular clouds from different environments and compare them to our own Galaxy the Milky Way (MW). It also offers an opportunity to study molecular clouds without worrying about materials obscuring our line of sight as it is mostly the case in the MW. We have resolved molecular clouds to clump level and created a catalog of clumps in M33 for the first time using ALMA archival data. The GMCs were traced by 12CO(2-1), 13CO(2-1) and C18O(2-1). We derived different properties of these clumps and compared them to those done in other Local Group of galaxies.The molecular clouds resolved are at different evolutionary stages, giving insights of environmental variation in our clumps and their properties.

Abstract

Low and intermediate-mass stars evolve through the Post Asymptotic Giant Branch (post-AGB) phase before they reach the Planetary Nebulae stage. After leaving the Main Sequence, they undergo intense episodes of mass loss when in the Giant Branch and, then, they enter the post-AGB stage which is a rather puzzling stellar evolutionary phase . Also, it has a very short duration, of the order of a few thousand years at most, so the number of confirmed post-AGB objects is really small and, thus, our understanding of this elusive evolutionary stage is still very constrained. Post-AGB stars are characterized by infrared excesses and high luminosities. The publication of precise Gaia DR3 parallaxes made it possible to calculate accurate distances and to revise the derivation of luminosities for post-AGB candidates to discard objects outside the expected luminosity range. By identifying post-AGB stars or possible candidates from the literature, then searching for their Gaia DR3 counterparts and using available photometry, interstellar extinction, published spectroscopically derived temperatures or spectral types and parallax-based distances, we fitted their Spectral Energy Distributions (SED) and we estimated their luminosities and circumstellar extinctions. When compared to models, luminosity values allowed us to disclose objects that are likely post-AGB stars from other target types whose observational properties mimic those of post-AGB stars. The position of our selected sample on the Hertzsprung-Russell (HR) diagram allows direct comparison with updated post-AGB evolutionary tracks and an estimation of their masses and evolutionary ages. A summary of the so far obtained outcome will be here presented.

Trigonometric parallax and proper motion of Sagittarius A* measured by VERA using the new broad-band back-end system OCTAVE-DAS

Dr Tomoaki Oyama[1], Dr Takumi Nagayama[1], Dr Aya Yamauchi[1], Dr Daisuke Sakai[1], Prof Hiroshi Imai[2], Prof Mareki Honma[1], Yu Asakura[1], Dr Kazuhiro Hada[1], Prof Yoshiaki Hagiwara[3], Dr Tomoya Hirota[1], Dr Takaaki Jike[1], Dr Yusuke Kono[1], Syunsaku Suzuki[1], Prof Hideyuki Kobayashi[1], Prof Noriyuki Kawaguchi[1]

[1]NINS, National Astronomical Observatory of Japan. [2]Center for General Education, Institute for Comprehensive Education, Kagoshima University. [3]Toyo University

Abstract

We successfully measured the trigonometric parallax of Sagittarius A* (Sgr A*) to be 117 ± 17 micro-arcseconds (μas) using the VLBI Exploration of Radio Astrometry (VERA) with the newly developed broad-band signal-processing system named "OCTAVE-DAS." The measured parallax corresponds to a Galactocentric distance at the Sun of $R_0 = 8.5^{+1.5}_{-1.1}$ kpc. By combining the astrometric results with VERA and the Very Long Baseline Array (VLBA) over a monitoring period of 25 years, the proper motion of Sgr A* is obtained to be $(\mu_\alpha, \mu_\delta) = (-3.133 \pm 0.003, -5.575 \pm 0.005)$ mas yr^{-1} in equatorial coordinates, corresponding to $(\mu_l, \mu_b) = (-6.391 \pm 0.005, -0.230 \pm 0.004)$ mas yr^{-1} in Galactic coordinates. This gives an angular orbital velocity of the Sun of $\Omega_\odot = 30.30 \pm 0.02$ km s^{-1} kpc^{-1} . We find upper limits to the core wander, $\Delta\theta < 0.20$ mas (1.6 AU), peculiar motion, $\Delta\mu < 0.10$ mas yr−1 (3.7 km s^{-1}), and acceleration, a < 2.6 μas yr^{-1} (0.10 km s^{-1} yr^{-1}) for Sgr A*. Thus, we obtained upper mass limits of $\approx 3 \times 10^4$ $M_\odot$ and $\approx 3 \times 10^3$ $M_\odot$ for the supposed intermediate-mass black holes at 0.1 and 0.01 pc from the Galactic center, respectively.

Modeling open clusters in CMD: binaries, mass function, and dynamic effects

Dr Lu Li

Shanghai Astronomical Observatory, CAS

Abstract

As cradles of stars and building blocks of galaxies, open clusters (OCs) encode valuable information about star formation and galaxy evolution. Hence, precisely and robustly measuring the fundamental properties of OCs, including age, metallicity, distance, extinction, stellar mass function (MF), and binary properties, is of great importance. The field star contamination has long been a major obstacle. Here I will present a state-of-the-art Bayesian framework that models the color-magnitude diagram of an observed OC as a mixture of single stars, photometric unresolved binaries, and field stars. Its advanced statistics and comprehensive physical models enable the determination of all the OC properties simultaneously with unprecedented precision and permit exciting discoveries. This method enables us to build a comprehensive OC parameter catalog, in particular, including the MF and binary properties, which were unfeasible in conventional catalogs. Applying the method to Gaia data, we find clear evidence of dynamical evolution in OCs for the first time. Taking NGC3532 as the first example, we find that stars with smaller mass or in the inner region tend to have less low mass-ratio binaries. Using a larger OC sample, we unveil that the MF slope is evolving with cluster age: older OC has flatter MF (i.e., less low mass stars). This is because the dynamic encounters can destroy the low mass-ratio binaries (especially in the cluster center) and kick out low-mass stars. Finally, this method has a great potential to incorporate other stellar models or physical processes in OCs, such as stellar rotation or blue stragglers.

Abstract

Dusty stellar point sources contribute to stellar dust emissions and enrichment of galaxies such as the Magellanic Clouds (MCs). We applied supervised machine learning classifiers for dusty stellar point source classification in the MCs, including young stellar objects (YSOs) and evolved stars. We implemented typical algorithms to classify dusty stellar categories comprising YSOs, oxygen- and carbon-rich asymptotic giant branch stars (AGBs), red supergiants (RSGs), and post-AGB stars. In the following, we created synthetic samples based on the minority class using the Synthetic Minority Oversampling Technique (SMOTE) method to resolve the SAGE catalogs' imbalanced spectral counts. The classification accuracy of these sources, which include 619 spectral labeled counts, was assessed using infrared features and multiwavelength filters. Therefore, the Probabilistic Random Forest (PRF) classifier, a tuned Random Forest (RF), performed best among all the models applied before and after data augmentation with the SMOTE. We reached an accuracy of ~89 percent based on the recall metric for the spectral classification. In this study, using the SMOTE technique does not improve the accuracy of the best model for the CAGB, PAGB, and RSG classes; it stays at 100% and 88%, respectively. However, there are variations for the CAGB, OAGB, and YSO classes. We collected photometric labeled data with properties similar to the training dataset and classified them using the top four models with more than 87% accuracy. The labeled data is available for three dusty stellar types, YSOs, oxygen- and carbon-rich AGBs, due to the reliable accuracy we achieved for them in models.

The imprint of star-formation-driven outflows on the evolution of dwarf galaxies

Dr. Michael Romano

National Centre for Nuclear Research, Warsaw, Poland. INAF - Osservatorio Astronomico di Padova, Padova, Italy

Abstract

Feedback from stars and active galactic nuclei is one of the most important processes steering the baryon cycle in galaxies, i.e., the set of complex phenomena driving the interplay between gas, dust, and star formation in their interstellar medium (ISM). Such a feedback could be strong enough to produce galactic-scale outflows able to sweep the gas out of the galaxies, drastically shaping their evolution. We investigated the impact of star-formation-driven outflows in local, low-metallicity dwarf galaxies drawn from the Dwarf Galaxy Survey. We made use of Herschel observations to detect atomic outflowing gas in the high-velocity wings of [CII] 158 μm emission line profiles. We found that outflows are ubiquitous in these galaxies, with an average outflow efficiency of the order of unity, at odds with predictions from state-of-the-art chemical evolution models. We estimated that ~40% of the gas entrained by the outflows can be expelled from the ISM, significantly enriching the surrounding circumgalactic medium, and producing extended atomic gas and dust reservoirs around the galaxies. These results highlight the key role of stellar feedback in the baryon cycle of low-mass sources, and are crucial for calibrating cosmological simulations attempting to reproduce the processes ruling the evolution of these galaxies across cosmic time.

The Rise of r-Process in Dwarf Galaxies

Guilherme Limberg[1], Alexander Ji[2], Silvia Rossi[1]

[1]Universidade de São Paulo. [2]University of Chicago

Abstract

Multimessenger observations of gravitational wave event GW170817 of a neutron star merger (NSM), have confirmed that these sites are capable of producing copious amounts of heavy elements through the rapid neutron capture process (r-process). However, because NSMs are expected to be delayed by billions of years, it is unclear how much they can actually contribute to the chemical enrichment of galaxies. Prompt sources of r-process, such as exotic kinds of supernovae, are theoretically promising for producing heavy elements in the early universe, but observational evidence is lacking. One way to investigate which is the dominant source of r-process is to look at the chemical evolution of dwarf galaxies, which are relatively simple systems in comparison to the Milky Way. We studied the r-process signature in a disrupted dwarf galaxy in the form of a stellar stream in the Galactic halo, referred to as Wukong or LMS-1. Stars in Wukong/LMS-1 are much closer than classical surviving Milky Way satellites and are, hence, much brighter and amenable to high-resolution spectroscopy, which is necessary to detect the heaviest elements. We discovered that Wukong/LMS-1 is the first example of a galaxy that has been enriched in r-process elements predominantly by NSMs. This finding confirms that NSMs not only do happen, but are actually important contributors to the chemical evolution of galaxies. Future observations of additional disrupted and/or surviving dwarf galaxies will finally answer if NSMs alone contribute to all r-process across cosmic history of if prompt sources are also involved.

Mass-loss rates and dust production from cool evolved stars in the Local Group galaxies

Dr Atefeh Javadi[1], Dr Jacco van Loon[2]

[1]Institute for Research in Fundamental Sciences (IPM). [2]Keele University

Abstract

The final stages of stellar evolution are critical for the evolution of galaxies because the processed matter is returned to the interstellar medium (ISM). Furthermore, the feedback from cool evolved stars is in the form of dust grains that play an important role in the temperature regulation of ISM, chemistry, and formation of planets. To begin, to understand the mass-loss mechanism we: [1] carried out a census of cool evolved stars in the majority of Local Group galaxies via long-term monitoring surveys in optical and near-IR wavelengths [2] performed accurate modeling of spectral energy distribution (SEDs) to measure the excess infrared emission from dust produced by these stars and to quantify the amount of matter they return to the interstellar medium. In this paper, I first present the mass-loss rates of cool evolved stars in a wide range of masses to see how mass loss mechanism acts in different populations (RGBs, AGBs (M-type or carbon stars) and RSGs) and to investigate whether it differs in different environments. Then, I will discuss the ISM replenishment by mass-loss via cool evolved stars in different galaxies.

Global insight into the properties of Infrared bright galaxies via panchromatic SED modeling

Subhrata Dey

Astronomical Observatory of Jagiellonian University

Abstract

We present the detailed spectral energy distribution (SED) modeling of 14 local (ultra)luminous infrared galaxies (U/LIRGs) with outstanding photometric data from the literature covering ultraviolet-far-infrared and radio bands (~50 MHz to ~30 GHz). We employ the CIGALE SED fitting code for ultraviolet--far-infrared--radio SED modeling. For radio-only SED modeling, we use the UltraNest package, leveraging its nested sampling algorithm. Combining results from our previous study on 11 LIRGs, we discuss the global astrophysical properties of a sample of 25 starburst galaxies ($z<0.5$). Their radio spectra are frequently characterized by bends and turnovers, with no indication of ULIRGs exhibiting more complicated SEDs than LIRGs despite showing more signs of interactions. Including radio measurements in CIGALE modeling constrained the dust luminosity and star formation rate (SFR) estimates by more than one order of magnitude better than previously reported for starburst galaxies. We show that total and nonthermal radio luminosity at 1.4 and 4.8 GHz frequencies can be good estimators of the recent SFR for all LIRGs and those ULIRGS with insignificant AGN influence. A weaker but still significant correlation is observed between radio SFR at 1.4 GHz and old (averaged over 100 Myr) SFR based on SED modeling, indicative of multiple episodes of starburst activity during their lifetime. The thermal radio luminosity at 4.8 GHz is a better tracer of recent star formation than the thermal luminosity at 1.4 GHz.

Multi-Screen scattering in Fast Radio Bursts to probe extragalactic ISM

Mr. Sachin Pradeep Etakkepravan Thulicheri

Max Planck Institute for Radio Astronomy

Abstract

Fast Radio Bursts (FRBs) are known for their scintillation and scattering phenomena, often attributed to multiple screens within the interstellar medium (ISM). These plasma screens, spanning from 1-100 AU in scale, cause multipath propagation and angular broadening of single pulses. When two screens appear "pointlike" to each other, they scintillate on both small and large scales, aiding in constraining scattering to FRB host galaxies.In this study, we use simulations to explore this regime, revealing that when one screen resolves the other, it quenches Milky Way scintillations.

We introduce a new theoretical framework to study multi-screen scattering of single pulses, considering the cosmological nature of FRBs and the screens involved. Our primary goal is to understand how pulses appear when screens resolve each other, allowing us to distinguish such systems.

Simulations show that changes in the scintillation pattern over time in the dynamic spectra of the pulse I(t,v) is the key. Moreover, we propose an updated formula for locating the host galaxy screen from the FRB source, giving insights into probing extragalactic ISM structures at AU scales. This approach also opens up avenues in calculating the velocities of such plasma screens, particularly when a sufficient number of bursts allows for the analysis of secondary spectra.

An intriguing prospect is the use of such screens as cosmic lenses to constrain emission region sizes from pulsars, FRBs, and other coherent emissions from neutron stars. Through simulation studies, we have devised a novel observational technique for this purpose.

New Candidate Proplyds in the Orion NGC 1977 and NGC 2024 Clusters

Dr. Ryan Boyden

University of Virginia. Space Science Institute

Abstract

I will present new results from my VLA programs that aim to constrain the photoevaporative mass-loss rates of protoplanetary disks in the Orion NGC 1977 and NGC 2024 clusters. Both clusters were recently found to host populations of externally evaporating disks (i.e., “proplyds”), but the HST observations used to discover these photoevaporating disks only targeted a small area of each cluster. My VLA programs have mapped all of NGC 1977 and NGC 2024 at high sensitivity and high angular resolution over multiple radio continuum bands, allowing for the first systematic search of photoevaporating disks in clustered star-forming regions with less extreme radiation environments than the Orion Nebula Cluster. We identify several-dozen new candidate proplyds in NGC 1977 and NGC 2024, as evidenced by their centimeter-wavelength morphologies and free-free emission spectra. We measure the photoevaporative mass-loss rates using the observed brightness of the free-free emission, and find typical mass-loss rates of ~10^(-8) Msun/yr. These mass-loss rates, combined with the discovery of additional proplyds in each region, indicate that disks in NGC 1977 and NGC 2024 are impacted by the external environment, but to a lesser degree than disks in the Orion Nebula Cluster. Overall, this study highlights the importance of external photoevaporation over a range of cluster conditions, and it lays the groundworks for future studies of disk photoevaporation that will be achievable in more distant, yet more typical, star-forming clusters with next-generation radio interferometeric facilities like SKA and, eventually, ngVLA.

Comprehensive Compilation of Stellar Data in M33's Central Region: Unveiling the Final-Stage Evolution Through Near-Infrared Survey

ms Mina Alizadeh[1,2], Dr. Atefeh Javadi[2], Prof. Jacco Van Loon[3], Dr. Yousef Ali Abedini[1], Dr. Hedieh Abdollahi[2]

[1]University of Zanjan. [2]IPM (Institute for theoretical Physics and Mathematics). [3]Keele University

Abstract

We obtained data using three cameras at the UK InfraRed Telescope (UKIRT) between 2003 and 2007. The observations in the K-band were conducted by the UKIRT Fast-Track Imager (UFTI) over three consecutive nights in August 2005. The Wide Field Camera (WFCAM) data in the J and H bands were collected between 2005 and 2007. Additionally, UIST data in the K-band for the central region of M33 were gathered from 2003 to 2007.

Our focus was on stars in the final stage of their evolution, where luminosity is more directly related to birth mass. By combining data from multiple instruments and projects, we aim to identify long-period variables in the galaxy's central region, as this area provides the deepest and most comprehensive investigation of the galactic center due to the nature of the data. The identification of variables will involve photometry on the WFCAM data with PSF calibration followed by a re-examination of the data.

Novel Chemical Abundance Measurements with JWST MIRI/MRS

Dr. Noah Rogers[1], Dr. Evan Skillman[2], Dr. Danielle Berg[3], Dr. Rick Pogge[4], Dr. Karla Arellano-Cordova[5]

[1]CIERA, Northwestern University. [2]University of Minnesota - Twin Cities. [3]University of Texas at Austin. [4]The Ohio State University. [5]University of Edinburgh

Abstract

Gas-phase chemical abundances are powerful tracers of star formation and galactic evolutionary mechanisms. To constrain the overall metallicity of the interstellar medium, many prior galaxy surveys have relied on strong-line abundance diagnostics, which relate the emission of intense optical collisionally-excited lines to the O/H abundance in a nebula. However, these diagnostics have been shown to have large variation and discrepancies when calibrated on empirical or photoionization model data. One alternative is to utilize the IR fine-structure lines, which are insensitive to the electron temperature and reddening, and which accurately probe gas-phase abundances/ionization conditions. We present new JWST MIR observations of multiple extragalactic H II regions in the spiral galaxies M33 and M101 with prior direct T_e and abundance measurements from the CHAOS survey. We provide the first empirical calibration of Ne_{23}, a novel MIR abundance diagnostic that can infer O/H in high-metallicity or obscured environments from the MIR Ne fine-structure lines and H I recombination lines. We employ other intense fine-structure emission lines to directly calculate the gas-phase abundance of Ne, S, and Ar from all relevant ionization states. The total abundances of these alpha elements are compared to the optical abundance measurements to assess the validity of ionization correction factors that are commonly adopted for chemical abundance inferences in local and high-z galaxies.

Ages and metallicities of stellar clusters using S-PLUS narrow-band integrated photometry: the Small Magellanic Cloud

Gabriel Fabiano de Souza, Guilherme Limberg

Universidade de São Paulo

Abstract

The Magellanic Clouds are irregular dwarf-galaxies and are among the largest and closest of the Milky Way, with stars covering every age. This makes them an important laboratory for validating methods to understand the evolution of stellar populations and their star-formation processes, which can then be applied to more distant galaxies. In this work, the characterization of the populations of a set of stellar clusters of the Small Magellanic Cloud (SMC) is made, for the first time, using the Southern Photometric Local Universe survey (S-PLUS). Through its 7 narrow bands centered on important spectral lines, we can obtain more information about stellar populations, also counting on 5 broad bands similar to those of the Sloan Digital Sky Survey. Two methods were used to determine ages and metallicities. The first was done by adjusting S-PLUS observed colors to the colors of simple stellar population models. The second was BAGPIPES, which fits spectral energy distributions in a Bayesian framework. Both methods were validated to stellar clusters of the SMC whose parameters are well known and that have S-PLUS photometry and then applied to new determinations in the SMC.

Galactic Supernova Candidates Discovered by MeerKAT

Dr. Loren Anderson

West Virginia University

Abstract

It is well-known that the census of Galactic supernova remnants (SNRs) is incomplete. This incompleteness is thought to arise from difficulties locating Galactic SNRs due to confusion (mainly with HII regions) and a lack of sensitivity. Recent works have shown that sensitive radio continuum data, when combined with data in the mid-infrared (MIR), can identify new SNR candidates. While thermally-emitting HII regions have strong MIR and radio continuum emission, non-thermally emitting SNRs are deficient in MIR emission. We here discuss our recent work with new 1.3 GHz South African Radio Astronomy Observatory (SARAO) MeerKAT Galactic Plane Survey continuum data to identify new SNR candidates in the inner Galaxy. The MeerKAT data boast an angular resolution of 8" and are sensitive to a wide range of size scales, making them ideal for SNR searches. We have identified nearly 200 new SNR candidates and objects of interest. SNR candidates identified using the MIR/radio continuum criterion require additional information to confirm that they are true SNRs, namely determination of negative spectral indices, detection of polarized radio continuum emission, or association with high-energy emission. If confirmed, these SNR candidates would increase the known Galactic SNR population by ~50%.

Constraining the icy origin of H_2CO in Protoplanetary Disks

Mr. Claudio Hernández-Vera[1,2], Dr. Viviana Guzmán[1], Dr. Anna Miotello[2], Dr. Ilse Cleeves[3]

[1]Pontificia Universidad Católica de Chile. [2]European Southern Observatory. [3]University of Virginia

Abstract

Protoplanetary disks are considered a material reservoir for planetary assembly. Hence, resolving the spatial distribution of complex organic molecules (COMs) in protoplanetary disks is crucial in estimating the potential habitability of other worlds. Unfortunately, a significant portion of the organic inventory is thought to be locked on the surface of dust grains, mostly the O-bearing COMs. In this case, smaller but brighter tracers like formaldehyde (H_2CO) could be used. H_2CO is a small organic molecule considered a precursor of O-bearing COMs on the icy surfaces of dust grains, but gas-phase reactions can also form it. Since the specific contribution of each mechanism is poorly constrained, determining the dominant formation pathway of H_2CO is necessary for setting up its potential as a tracer of the cold reservoir in protoplanetary disks. In this context, we present spectrally and spatially resolved ALMA observations of several H_2CO lines toward the bright Herbig Ae protoplanetary disk HD 163296. We determined the excitation conditions of H_2CO as a function of disk radius and put constraints on the height of H_2CO emission to get clues about its formation. In contrast to TW Hya, a T Tauri disk where the cold gas-phase chemistry is expected to predominate, a significant contribution from dust-grain surface chemistry cannot be discarded in HD 163296. Additionally, to obtain more representative statistics of H_2CO formation, we complement our analysis with the early results from the DECO ALMA large program, thus adding an extensive sample of 80 protoplanetary disks with multiple H_2CO transitions.

Protostars and young disks with JWST

Ewine van Dishoeck

Leiden Observatory, Leiden University, the Netherlands. Max Planck Institute for Extraterrestrial Physics, Garching, Germany

Abstract

Understanding how stars and planets are built requires observations at long wavelengths in order to penetrate their dusty natal clouds. Webb is orders of magnitude more sensitive than previous missions and has subarcsec resolution in the infrared. Webb is therefore eminently suited to study the physical and chemical structure of embedded protostars and disks. In addition to jets and outflows, rich ice spectra are seen in the cold outer envelopes of protostars providing evidence for the presence of simple and complex molecules in ices, including salts. In addition, gaseous molecules such as CO, CO2 and water are seen in the mid-infrared spectra. These lines can be used to probe the composition of hot cores and young disks in the embedded stage and compare this with results found around T Tauri stars, whose rich spectra show many lines from gaseous molecules including surprising new hydrocarbon molecules. Together they point to a rich chemistry with a varying composition and C/O ratio that may be linked to stellar mass and to the physical structure of the system. Results from the first year of observations of the JOYS+ program will be presented. See miri.strw.leidenuniv.nl for more details.

Dust evolution across PDRs using JWST data

Dr Meriem Elyajouri

Institut d'Astrophysique Spatiale (IAS), Université Paris Saclay, CNRS

Abstract

Using JWST spectro-imaging, we conducted a quantitative analysis of the observations from two photon-dominated regions (PDRs) with different physical conditions: The Orion Bar (ERS PDRs4All [1]) and Horsehead Nebula (GTO 1192, [2]).

Our analysis with the THEMIS dust model [3] and the SOC radiative transfer model [4] resolved, for the first time, the very strong density gradient and revealed unprecedented constraints on the properties of dust grains: depletion of nano-grains in the atomic region and variations in the hydrogenation of nano-grains in different regions of the PDRs [5].

These constraints truly challenge our understanding of the physics and chemistry of PDRs, given that nano-grains are responsible for the majority of UV radiation attenuation, gas heating via the photoelectric effect, and the formation of H2 on their surface. In conclusion, We showed that it is not possible to reproduce the observations in the PDRs using grains from the diffuse interstellar medium. Therefore, it is necessary to evolve the grains by altering their properties to understand the observations in PDRs.

On the Formation of Massive Stars in Filamentary Clouds: Importance of Edge Collapse Process

Dr. Naval Kishor Bhadari, Dr. Lokesh Kumar Dewangan

Physical Research Laboratory, Ahmedabad

Abstract

Recent studies, utilizing infrared and millimeter observations of the interstellar medium (ISM), have unveiled a complex network of dusty and gaseous filaments closely associated with star-forming regions. How these filaments play a role in star formation processes is one of the hot topics of debate in astronomy. Our recent investigations, utilizing multiwavelength data, have shed light on a rarely observed physical process in isolated filaments named "end-dominated collapse (EDC)," demonstrating its pivotal role in mass assembly for the formation of star clusters including massive stars. The EDC process, propelled solely by filament self-gravity, leads to the formation of dense clumps at the ends of the filament. Thus far, a handful of EDC filaments are observed and raised questions on the commonality of this process in filaments. We have identified three such potential filaments: Monoceros R1 (length ~14 pc, mass ~1465 Msun), a Giant molecular filament (GMF) G45.3+0.1 (length ~75 pc, mass ~1.1 × 10^6 Msun), and IC 5146 dark Streamer (length ~8 pc). Additionally, the configuration of multiple converging small-scale sub-filaments (~1-5 pc), known as hub-filament systems (HFSs), is primarily observed at the ends of the filament. Our study also unveils a new observational proxy of the EDC process as the bending of magnetic field lines at the end of filaments. This presentation provides a comprehensive overview of recent progress in this area and the importance of the EDC process along with HFSs in massive star formation.

Role of Magnetic fields in Star-formation: New Insights into the Galactic 'Snake' IRDC G11.11-0.12

Mr Omkar Jadhav[1], Dr. Lokesh Kumar Dewangan[2]

[1]Physical Research Laboratory, IIT Gandhinagar. [2]Physical Research Laboratory

Abstract

Observational studies indicate Infrared Dark Clouds (IRDCs) are significant for understanding massive star and protostar formation, with magnetic fields playing a key role in their stability. However, their exact role in the early stages of star formation remains unclear. Our study focuses on the Galactic 'Snake' IRDC G11.11-0.12, using SOFIA HAWC+ 214 µm polarimetric data, allowing us to study the plane of the sky (POS) magnetic field (B-field) morphology. We observe perpendicular B-field orientations across the cloud G11, with a notable shift towards the center. We generated a POS B-field map using the Davis-Chandrasekhar-Fermi Method and computed mass-to-flux ratios, revealing both subcritical and supercritical regions in the cloud. The local gravitational field vectors are also calculated towards the cloud using the 214 µm intensity map. However, embedded protostars are found toward the entire cloud. Interestingly, dust condensations hosting previously known high-mass protostellar candidates p1 and p6 seem to be subcritical and supercritical, respectively. Our analysis of the cloud's Position-Position-Velocity map revealed large-scale periodic velocity oscillations. In comparison with the existing Gravitationally Induced (GI) core-collapse model, it was observed that the detected oscillations arise from a combination of the kinematics associated with the GI core collapse model and the oscillation of large-scale physical filaments. The existing JWST near-infrared images reveal a hub-filament configuration (below 10000 AU) around p1 and p6, where new embedded sources are investigated, which are not detected in the existing highly sensitive IR surveys. In this presentation, I will provide a more thorough analysis of our findings.

Dust distribution in the Galactic plane using interstellar polarimetry

Dr Namita Uppal, Prof Shashikiran Ganesh

Physical Research Laboratory, Ahmedabad, India

Abstract

Dust, despite constituting only 1% of the mass of the interstellar medium, has a profound effect on our view of the Galaxy. It is majorly confined within the disk of the Galaxy, making it an ideal candidate for investigating the Galactic structure, particularly the spiral arms. Interstellar dust emits thermal radiation primarily in the longer wavelengths, where the effect of extinction is minimized. Studying the three-dimensional dust distribution in the Galaxy at longer wavelengths may cause discrepancies due to distance ambiguity and assumptions of Galactic rotation models.

Instead of directly tracing dust at longer wavelengths, we aim to investigate the efficacy of the ISM polarization in combination with Gaia distances as an indirect probe for the line of sight dust distribution. We conducted the R-band polarization observation of fifteen Galactic open-clusters distributed roughly in three lines of sight. The clusters were selected at varying distances to infer the number of dust layers present along each line of sight. The observations were conducted using Imaging polarimeters, EMPOL (EMCCD-based POLarimeter) and AIMPOL (ARIES IMaging POLarimeter) available on 1.2m and 1.04m telescopes, respectively hosted by the Physical Research Laboratory and Aryabhatta Research Institute of Observational Science, India. Through careful observation strategies and meticulous data reduction, our study has revealed indications of local and global features, like spiral arms of the Galaxy. These findings highlight the significance of polarization observations for studying the Galactic structure and strongly justify the need for a dedicated polarisation survey to be carried out in the entire Galactic plane.

A new insight on the dust properties of low surface brightness galaxies

Dr. Junais Junais

National Centre for Nuclear Research (NCBJ), Warsaw, Poland

Abstract

Low surface brightness galaxies (LSBs) contribute a large fraction to the number density of galaxies, but their properties are still poorly known. LSBs are often considered dust poor, based only on a few studies. We use, for the first time, a large sample of LSBs and high surface brightness galaxies (HSBs) with deep observational data to study their dust properties. Our sample consists of 1631 optically selected galaxies at z<0.1 from the North Ecliptic Pole (NEP) wide field. We use the large set of data available in this field, from UV to FIR. By performing a spectral energy distribution fitting, we found that the majority of LSBs in our sample have negligible dust attenuation (Av < 0.1 mag), except for about 4% of LSBs that show significant attenuation with a mean Av of 0.8 mag. We found that these LSBs also have a high r-band mass-to-light ratio (M/Lr>3 Msun/Lsun), and show similarity to the extreme giant LSBs from the literature. This work provides a large catalog of LSBs and HSBs with detailed measurements of their several optical and infrared physical properties. Our results suggest that the dust content of LSBs is more varied than previously thought, with some of them having significant attenuation making them fainter than their intrinsic value. This will have serious implications for the observation and analysis of LSBs with current/upcoming surveys like JWST and LSST.

Cosmic-ray propagation and feedback in star-forming environments

Dr Lucia Armillotta[1], Prof. Eve Ostriker[1], Dr Yan-Fei Jiang[2]

[1]Princeton University. [2]Center for Computational Astrophysics, Flatiron Institute

Abstract

In recent years, there has been a growing interest in understanding the role of cosmic rays (CRs) in shaping galaxy evolution. MHD galaxy simulations including CRs have demonstrated that they may significantly contribute to the dynamics of the interstellar medium (ISM), regulating the level of star formation and driving large-scale outflows. However, the degree to which CRs influence these phenomena is highly contingent upon the chosen CR transport prescription within the model. To address this issue, we have recently developed a transport prescription that is grounded in physical principles rather than empirical considerations, aiming for a more realistic representation of CR physics in ISM simulations. This novel prescription has been employed to compute the propagation of CRs in three different galactic environments typical of nearby disk galaxies reproduced by the TIGRESS simulations. Together, the three simulated environments cover a wide range of gas surface density, gravitational potential, and star formation rate (SFR). Our results show that in the disk region the CR pressure to gas pressure ratio decreases with increasing SFR. The dynamical impact of CRs is therefore expected to increase in environments with lower SFR. Predictions from the simulations suggest limited support against gravity for most of the ISM mass near the midplane, but notable impacts on extraplanar dynamics (i.e., galactic fountains/winds).

Probing the star cluster population to trace the star formation history of Arp 147

Ms Miora Rakototafika[1], Mrs Zara Randriamanakoto[2]

[1]University of Antananarivo. [2]SAAO

Abstract

Collisional ring galaxies (CRGs) are rare and peculiar objects that offer insight into young massive star cluster (YMC) formation and evolution mechanisms. Studying star clusters in CRGs can provide valuable information about the galaxy star formation history and a better understanding of the earliest phases of star formation. We report a photometric study of YMC complexes in the CRG Arp 147 with the aim to assess the influence of the host environment on the star cluster properties and star formation mechanisms. We use HST BRI-band observations (PSF ~ 0.15") to derive the ages and masses of the star-forming knots and clumpy regions. By fitting our photometric catalogue to SSP models such as Yggdrasil and Starburst99, we find that the majority of the YMCs spread across the ring have ages < 10 Myr and masses > 10^5 $M_\odot$. The flat azimuthal distribution of the cluster ages points toward a popcorn star formation scenario, ie. there is no expected age gradient along the ring. We also estimate the number stars that form in bound clusters, known as cluster formation efficiency Γ. In the case of Arp 147, Γ > 20% which is in agreement with a new starburst activity triggered by the head-on collision happening 50 Myr ago. Overall, our findings imply that the cluster population of the CRG consists of a mix of pre-collision and post-collision YMC complexes, and with their properties likely affected by their host environment at least on sub-galactic scales.

Extinction Map Construction and Extinction Law Calculation of Nearby Galaxies

Dr. Yuxi Wang

Department of Astronomy, Qilu Normal University

Abstract

Interstellar extinction refers to the absorption and scattering of starlight by dust. The multi-band extinction laws are crucial to recover the intrinsic energy
distribution of celestial objects and infer the characteristics of interstellar dust. Meanwhile, extinction maps of galaxies contribute to the dust distribution
in galaxies and the structure of galaxies and are essential tools to study the stellar population and the star formation history in galaxies. The current studies
of extinction in nearby galaxies are limited to a few galaxies. As a result, there is large uncertainty about the nature and dust distribution, stellar population,
and star formation history of nearby galaxies. By introducing the dust model to simulate the effect of dust on stellar radiation innovatively, this project plans
to: (1) construct dust extinction maps of nearby galaxies with member stars as tracers, and analyze the dust distribution in different galaxies; (2) calculate
the multiband extinction laws toward more sight lines in the Large Magellanic Cloud, the Small Magellanic Cloud, and other nearby galaxies with blue supergiants
as extinction tracers, and analyze the dust properties in different interstellar environments; (3) predict the multiband extinction toward different sight lines in
nearby galaxies by combining the obtained extinction maps and extinction laws and provide extinction corrections for the observation of the Chinese Survey Space
Telescope (CSST) and related scientific objectives.

Structure, Extinction and Properties of Nearby Molecular Clouds

Zhetai Cao, Professor Biwei Jiang

Beijing Normal University

Abstract

Molecular clouds (MCs), as the star birthplaces, are generally dense that causes high extinction. A precise estimation of the extinction with distance is crucial to revealing the structure and understanding the dust properties in various star-forming environments. The nearby MCs to be studied in this work, specifically the Taurus MC (hereafter TMC), Orion MC (OMC), Perseus MC (PMC), represent different including massive and low-mass star-forming environments. With precise measurements and large quantity of tracers, a 3D dustmap of MCs can be calculated within 600pc, and the extinction curve from ultraviolet to infrared for single MCs instead of overlapped MCs along sightline can be studied and compared in different extinction levels and different environments. Besides, there exists a significant differences of ice absorptions in different MCs, which can be promoted into a large area.

Pre- and protostellar cores in the 200 brightest Planck compact sources

Andras Peter Joo[1], David Eden[2], L. Viktor Tóth[1]

[1]Eötvös Loránd University Budapest, Department of Astronomy. [2]Armagh Observatory and Planetarium, College Hill, Armagh

Abstract

The Planck compact source catalogue provides excellent samples for studying the earliest phases of star formation. Covering all galactic longitudes and latitudes they can give an overview of how star formation varies throughout the Milky Way, enabling a better insight into star formation out of the Galactic plane, where our current understanding is restricted mostly to nearby clouds. We examined the 200 brightest Planck compact sources visible from the northern hemisphere using observations from the James Clerk Maxwell Telescope's SCUBA2 bolometer array. Its high resolution revealed diverse, mostly filamentary structures, and allowed the extraction of point sources from the maps. We classified more than 1500 of these point sources and compiled a catalogue with their positions, sizes, and physical parameters. In our statistical analysis, we investigate properties of star-forming regions at different latitudes, aiming to better understand the flow of interstellar matter in the Galaxy and thus refine our latest view of the Milky Way.

The ngVLA as a gamechanger

Dr. L. Viktor Tóth[1,2], Dr. Mika Juvela[3], Dr. Eric Murphy[4]

[1]Eötvös Loránd University Budapest. [2]University of Debrecen. [3]Helsinki University. [4]NRAO

Abstract

The Next Generation Very Large Array (ngVLA) is one of the main astronomical infrastructure projects expected to achieve full operations in the 2030s. In this talk, a brief summary of the technical and scientific capabilities of the ngVLA will be presented. The ngVLA receiver systems will cover a wide range of frequencies (1.2–116 GHz) with large instantaneous bandwidths. With its high sensitivity and high angular resolution, it will complement the radio-frequency coverage of ALMA and SKA. Examples will be shown to demonstrate the ngVLA's abilities to observe the continuum and line emission of the interstellar medium in the northern sky. Simulation results for basic transitions of several key molecules will be also presented.

Abstract

Ultra-diffuse galaxies (UDGs) are attractive candidates to probe cosmological models and test theories of galaxy formation at low masses; however, they are difficult to detect because of their low surface brightness. In the Local Group a handful of confirmed and candidate UDGs have been found to date, most of which are satellites of the Milky Way and M31, and only three are isolated galaxies. It is unclear whether so few UDGs are expected. We address this by studying the population of UDGs formed in hydrodynamic constrained simulations of the Local Group from the HESTIA suite. For a Local Group with a total enclosed mass, M (< 2.5 Mpc) = 8×10^{12} $M_\odot$, we predict that there are 12 ± 3 isolated UDGs (68% confidence) with stellar masses between 10^6 and 10^9 $M_\odot$, and effective radii $R_e \geq 1.5$ kpc, within 2.5 Mpc of the Local Group, of which 2^{+2}_{-1} (68% confidence) are detectable and classified as UDGs in the footprint of the Sloan Digital Sky Survey (SDSS). Accounting for survey incompleteness, we find that almost the entire population of UDGs in the Local Group field would be observable in a future all-sky survey with a depth similar to the SDSS, the Dark Energy Survey, or the Legacy Survey of Space and Time. Our results suggest that there is a population of UDGs in the Local Group awaiting discovery.

Radiative transfer modelling of nearby face-on spiral galaxies

Mr Christopher Inman[1], Prof Cristina Popescu[1], Dr Mark Rushton[2], Dr David Murphy[1]

[1]University of Central Lancashire. [2]Astronomical Institute of the Romanian Academy

Abstract

Radiative transfer models are ideal tools for decoding the spectral and spatial energy distribution of galaxies. Yet, because of the complexity and computational demands involved, until recently, only a couple of individual star-forming galaxies had been modelled in detail using this procedure. Here we present the modelling of a small sample of face-on nearby galaxies with detailed imaging information in the UV/optical/MIR/FIR/submm spectral range: M33, M51, NGC628, NGC3938, M101 and the LMC. We show that we can successfully account for the panchromatic imaging data. We derive the spatial distribution of Star-Formation Rate, stellar mass, specific star formation rate, dust mass, dust attenuation and radiation fields and discuss the implications of these results for our understanding of the star formation process in galaxies. We review the challenges, advances and future perspectives in the field.

Dust polarization observations tracing magnetic fields in nearby galaxies

Rosita Paladino

INAF - IRA Bologna

Abstract

The properties of the multi-phase interstellar medium (ISM) in nearby galaxies can be nowadays investigated with unprecedented accuracy, thanks to the current observational facilities.

Among the components of the ISM, magnetic fields are the most difficult to detect, since they cannot be observed directly, but specific observations are needed to measure their effects.

To date, large-scale magnetic fields in external galaxies have mostly been probed through polarized synchrotron radiation, due to ultra-relativistic electrons spiralling along magnetic fields lines. These observations trace mostly the warm gas in the galaxies halos.

Dust polarization, due to the alignment of dust grain with magnetic fields, observed at far-IR - sub-mm frequencies, can also be used to trace magnetic fields in the cold and dense gas component.

Many observations of dust polarization are available for Milky Way dense regions, although complicated from our position inside the Galaxy.

Nearby galaxies allow a view from outside and observations of dust polarization at cloud scales are very important to trace magnetic field across the hierarchy of spatial scales involved in star formation and through the multiple phases of the interstellar medium.

ALMA, with its unprecedented combination of sensitivity and resolution in full-polarization observations at submm wavelengths, allows for the first time to observe dust polarization and magnetic field structure at spatial scales of giant molecular clouds in nearby galaxies.

I will provide an overview on the technical challenges of full polarization observations with ALMA, and highlight some recent results obtained studying dust polarization in the nearby Universe.

WISDOM: Molecular cloud properties and star-formation efficiency

Prof Martin Bureau

University of Oxford

Abstract

Using observations from the WISDOM survey that spatially resolve (1-30 pc) individual molecular clouds across the Hubble sequence, we reveal a clear dependence of the nature of the molecular interstellar medium of galaxies on Hubble type, and present a simple diagnostic of cloud formation. In particular, i) we highlight the shortcomings of the usual virial approach to clouds as self-gravitating objects, and stress the importance of the external galactic potential and in-plane shear to regulate the dynamical states of clouds. ii) We also introduce a simple but powerful cloud-cloud collision formalism that accounts for the cloud properties in both nearby and high-redshift systems. iii) We reveal much steeper size - linewidth relations in the inner parts of barred disc galaxies. Finally, using observations of the ionised gas from the SITELLE instrument, we discuss the impact of these different mechanisms on the star formation efficiency of the clouds and thus the quenching of star formation, particularly in galaxy nuclei and spheroids (morphological quenching).

The state of the HCN/H13CN ejecta of V4334 Sgr (Sakurai's star)

Dr. Daniela Barria[1], Prof. Stefan Kimeswenger[2,3]

[1]Universidad Central de Chile, Avenida Francisco de Aguirre 0405, La Serena, Coquimbo, Chile.. [2]Universität Innsbruck, Institut für Astro- und Teilchenphysik, Technikerstr. 25, 6020 Innsbruck, Austria. [3]Universidad Católica del Norte, Avenida Angamos 0610, Antofagasta, Chile.

Abstract

It is assumed that about 10-20% of the central stars of planetary nebulae (PN) undergo a very late thermal pulse (VLTP). This phenomenon is so violent that the pre-white dwarf star briefly reverts to the asymptotic giant branch and becomes a "born-again" red giant, which then undergoes a second PN stage. The ejecta of this last phase are extremely H-poor, hosted inside the evolved H-rich PN. V4334 Sgr (Sakurai's star) is one of the only two objects caught in this rapid and rare evolutionary stage in the last century, and it is the only star that has been observed with modern nowadays instruments. It experienced the VLTP on the white dwarf cooling track in the early 1990s. Since then it has been observed at almost all wavelengths. However, the dense dusty cocoon obscures the rapid stellar evolution of the nucleus in the visual and near-infrared range. Radio observations are therefore one of the cornerstones of the investigation.

In this work, we will present our results on the state of the molecular HCN and H13CN ejecta of the circumstellar envelope of V4334 Sgr, which we derived from APEX observations of 2019. We used three transition lines of HCN and H13CN each, taken within a few days. This allowed us to derive physical properties such as density, optical depth, temperature, and the carbon isotope ratio in the cool ejecta of this unique target.

The Age-Dependent Vertical Actions of Young Stars in the Galaxy

Domenica Garzon[1], Dr. Neige Frankel[2], Dr. Eleonora Zari[3], Dr. Maosheng Xian[4], Dr. Hans-Walter Rix[3]

[1]University of Illinois Urbana-Champaign. [2]Canadian Institute for Theoretical Astrophysics, University of Toronto. [3]Max Planck Institute for Astronomy. [4]Beijing Normal University

Abstract

Stars in the Galactic disk are born on cold, nearly circular orbits confined to the midplane of the disk. Over time, these orbits change due to small or large-scale perturbations. Understanding the vertical motions of stars in the Galactic disk is pivotal for deciphering the dynamical and evolutionary history of the Milky Way. Such heating phenomena are well-constrained for old stars in the Galactic disk. But what happens to the orbits of stars shortly after they are born? We investigate the vertical motions of young stars using a sample of OBA stars from Gaia E/DR3 and LAMOST. We quantify the relation between stars' mean vertical actions and their ages as a function of Galactocentric radii. While this trend suggests a phenomenon known as "heating," other dynamics within the galactic disk might offer different interpretations.

Large-scale H-alpha emission in the M81 group of galaxies discovered by the pathfinder Dragonfly Spectral Line Mapper

Dr. Deborah Lokhorst[1], Seery Chen[2], Prof Bob Abraham[2], Imad Pasha[3], Prof. Pieter van Dokkum[3]

[1]NRC Herzberg Astronomy & Astrophysics Research Centre. [2]University of Toronto. [3]Yale University

Abstract

We present deep wide-field H-alpha and [NII] imaging of the M81 group of galaxies, which was collected by the latest evolution of the Dragonfly Telephoto Array: the pathfinder Dragonfly Spectral Line Mapper. The Dragonfly Spectral Line Mapper is an ultra-narrow bandpass imager built to directly image the circumgalactic media of local galaxies. The pathfinder imaging of the M81 group revealed a colossal cloud of ionized gas at the virial radius of M82, along with an abundance of ionized gas surrounding the M81 and M82 galaxies. We discuss potential origins of the cloud and its connection to the M82 starburst as well as implications for the star formation history and feedback in M82. The pathfinder imaging of the M81 group is just the tip of the iceberg, as the full Dragonfly Spectral Line Mapper has 40 times more collecting area than the pathfinder. The full Dragonfly Spectral Line Mapper finished commissioning at the end of 2023, and we are currently carrying out a survey of the circumgalactic medium of galaxies in the local Universe. We present the first results of this survey, which reveals H-alpha, [NII], and [OIII] emission around galaxies to an order of magnitude lower surface brightnesses than previously detected.

Discovery and study of the physical properties of high-mass prestellar cores

Discovery and study of the physical properties of high-mass prestellar cores Maxime Valeille-Manet

Laboratoire d'Astrophysique de Bordeaux

Abstract

The study of the early phases of high-mass star formation is a major topic in astrophysics that is still poorly understood. Here we survey for high-mass prestellar core candidates in the data cubes of massive proto-clusters mapped in the ALMA-IMF program at a resolution of 2700 au.

For this purpose, an automatized method for systematically detecting outflows from proto-stellar cores is developed, combining CO and SiO spectra and outflow maps. Cores without significant outflows are considered as excellent candidates to be prestellar cores.

We show that 43 cores with a mass greater than 8 Msol are such good prestellar candidates in the ALMA-IMF survey. They cover a mass range from 8 to 72 Msol, and for a total amount of around 51 high-mass proto-stellar cores in the survey. Among those 43 cores, 14 have a mass greater than 16 Msol and will most certainly form a high-mass star in the future.

We can then derive statistical lifetimes in several bins of mass with lifetimes below 10^5 yr for the most massive cores. We can conclude that the high-mass pre-stellar cores are rare with short statistical lifetimes. But on the other hand, when we compare with the typical free-fall times inside the detected cores, the obtained lifetimes are relatively large with values of the order of 10 x T_ff. Such large values in terms of T_ff strongly suggest the need of a support against gravity to prevent the cores to collapse on a free-fall time as expected.

Inner structure of L1551 IRS5 binary system and its implication on the morphology at molecular outflow scales

Aurora Duran, Laurent Loinard, Pedro R. Rivera-Ortiz

Instituto de Radioastronomía y Astrofísica - UNAM

Abstract

Single star formation is well studied. However, most stars are formed in binary systems, which may affect the substructure architecture such as the circumbinary disk, inner and outer envelopes, and the outflow. Using the continuum data and the line of $C^{18}O$ (2 -1) obtained with ALMA at band 6, we studied the structure of the protostellar binary system L1551 IRS5 below 3000 AU. This object is a class I binary system with a period of 400 yr, located at the molecular cloud of Taurus (146 pc), with an estimated total mass of 1.1 M_{sun}, and two associated radio jets. We were able to identify the circumbinary disk and the circunstellar disk of each component of the binary, the inner envelope, and the cavity walls created due to the high velocity jets, in addition to updating some physical parameters.

Since the data reveal a particular structure consisting of filaments at the envelopes' scales connecting the outflow to the circumbinary disk, we suspect this structure is affected by the interaction between the binary components. Consequently, we constructed an analytical model that allows us to constrain the contribution of the binarity at the inner part and the outflow morphologies, comparing the observations with this new model.

Analytical model of the L1551 IRS5 outflow

Aurora Duran, Laurent Loinard, Pedro R. Rivera-Ortiz

Instituto de Radioastronomía y Astrofísica - UNAM

Abstract

Single star formation is well studied. However, most stars are formed in binary systems which may affect the substructure architecture and the outflow. We created an analytical model that can be used to predict the influence of the morphology of the outflow and a few dynamic features that can reproduce the emission observed in L1551 IRS5. This model consists of a jet with constant velocity which is moving in a constant direction from the origin. After some time the jet would have reached a certain length. As the jet moves, a part of the envelope will be pushed away due to the thermal pressure produced by the leading shock, and we assume that the lateral shock produced at any given point inside the outflow is ballistically ejected with a velocity perpendicular to the jet direction which will create the outflow locus. This analysis can help us to produce a data cube with position-position-velocity coordinates that can be compared morphologically to the observation, allowing us to explain and discern the outflow contribution from the complex emission due to the binary detected in the L1551 IRS5 system.

Abstract

Variability is one of the most important characteristics of forming stars, thus understanding physical mechanisms responsible for variability over a range of environments is crucial to understand the star formation process. With a subsolar metallicity and strong UV radiation, the Small Magellanic Cloud (SMC) provides us with an opportunity to study star formation in a significantly different environment than in today's Galaxy. We present the results of the study on the mid-infrared variability of young stellar objects (YSOs) in three star-forming regions of the SMC: N66, N83/N84, and N90. YSOs at a range of evolutionary stages have been identified in these regions by various techniques in multi-wavelength studies. Our analysis is mainly based on the Spitzer Space Telescope's "Young Stellar Object VARiability in the Magellanic Clouds" (YSOVAR-MC) program that imaged N66, N83/N84, and N90 in IRAC 3.6 and 4.5 microns bands. YSOVAR-MC consists of nine epochs of observations over 30 days, designed to capture time variations of the order of hours to weeks. We have constructed a nine-epoch YSOVAR-MC catalog for each region and combined it with additional epochs from other surveys (S^{3}MC, SAGE-SMC, SAGE-VAR, and SMC-Last), resulting in 13 epochs for N83/N84 and N90, and 17 epochs for N66 over 12 years. Using the multi-epoch catalogs and statistical methods, we identify variable intermediate- to high-mass YSOs and establish if the flux variations are periodic or stochastic. We compare our results to those of Galactic studies to investigate the dependence of global mid-infrared YSO variability characteristics on the environment.

Spatially resolved molecular line ratios in GATOS

Anelise Audibert

Instituto de Astrofísica de Canarias. Universidad de La Laguna

Abstract

Spatially resolved molecular line ratios offer crucial insights into changes in gas excitation resulting from AGN ionization, jets, and star formation. Our goal is to perform an excitation study of molecular gas in the Galactic Activity, Torus, and Outflow Survey (GATOS) survey, exploring signatures that differentiate winds from ambient ISM. We aim to model CO excitation, determining gas temperature, density, and volume using a radiative transfer code (e.g., RADEX). While three CO transitions are optimal, meaningful differences in line ratios can be detected with only two transitions. We identified public ALMA observations of CO(1-0), CO(2-1), and CO(3-2) with spatial resolution better than 0.8". For galaxies with JWST-MRS observations, we will incorporate warm molecular H_2 lines into our analysis. A case study on one the GATOS galaxies reveals that regions with higher excitation, traced by CO(3-2)/CO(2-1) with ALMA and H_2 S1/S3 with JWST, coincide with hot spots of the nuclear radio jet. This example illustrates that radio jets interacting with the gas induce distinct gas-excitation conditions, a phenomenon explored in only a few detailed resolved studies to date.

Exploring the Galactic latitude dependence of Faraday complexity in the SPASS/ATCA RM catalogue

Shilpa Ranchod

Max-Planck-Institüt für Radioastronomie

Abstract

Magnetic fields are an essential component of the interstellar medium, and measuring their structure and scale in the Milky Way is imperative for a holistic understanding of Galactic astrophysics. Large area legacy surveys of polarised extragalactic radio sources have provided an understanding of the large scale Galactic Faraday screen. With more sensitive follow-up observations of such catalogues, e.g SPASS/ATCA RM catalogue, we can fully understand their systematics to ensure continued legacy value into the SKA era. We report a latitude dependency of the Faraday complexity of polarised sources in this catalogue within 10 deg of the Galactic plane towards the inner Galaxy. We present higher resolution ATCA observations at 2.1 GHz to investigate this trend and measure the contamination of extended Galactic emission in the catalogue. We find an overall decrease in Faraday complexity in these sources with our higher angular resolution observations. With a complexity fraction of 42%, we establish that the majority of the complexity in the SPASS/ATCA sample is due to the mixing in of diffuse Galactic emission at scales $\theta > 2.8'$. Furthermore, we find a correlation between our observed small-scale complexity $\theta < 2.8'$ and the Galactic spiral arms, which we interpret to be due to Galactic turbulence or small-scale polarised emission. Our findings highlight the need to consider observations at various angular scales to fully interpret the physical scale of the Faraday complexity.

Chemical Evolution of M31 from HII Region Spectroscopy.

Chloe Bosomworth[1], Dr Jan Forbrich[1,2], Prof Charles Lada[2]

[1]University of Hertfordshire. [2]Center for Astrophysics | Harvard & Smithsonian

Abstract

Giant molecular clouds are the main sites of star-formation in galaxies and home to the majority of HII regions, which are photoionized by newly formed massive stars. Their gas-phase metallicities trace the latest stage of a galaxy's chemical evolution. From optical spectroscopy of HII regions in the Andromeda Galaxy (M31) with Hectospec/the MMT we have calculated metallicities (oxygen and nitrogen) for 294 individual HII regions and values for the radial gradients using strong-line methods. Consistent with recent work on other galaxies, we find statistically significant metallicity variations around the radial gradient. Subtracting the gradient, we find that enhanced and reduced abundance HII regions (compared to the radial gradient) are distributed across the entire disk. Enhanced-abundance HII regions suggest that these parts of the ISM have been enriched by recent star-formation/supernovae, whereas reduced-abundance HII regions are possible evidence that external low-metallicity gas was brought into the galaxy (possibly during a collision between with M32). We find that HII region metallicities are well-correlated at sub-kpc scales, but less well-correlated on kpc-scales. Finally, we have obtained deep CO measurements and the first dust continuum detections of resolved GMCs in an external spiral galaxy (M31) using the Submillimeter Array, which provided us with direct measurements of α'(12CO - dust) i.e., the crucial factor to convert CO emission to dust mass. Combined with the MMT survey, we obtain a first direct test of the metallicity dependence of α'(12CO - dust). Remarkably, we find no significant variation of α'(12CO - dust) with metallicity.

The GLOSTAR-VLA Galactic plane survey: VLA D-configuration radio source catalog

Dr. Sac Nicte Medina

Max Planck Institute for Radio Astronomy

Abstract

The GLOSTAR-VLA survey studies star formation in the Galactic plane between -2 < l < 60 deg and |b| < 1deg, and the Cygnus X region (76 < l < 83 deg and -1 < b < 2 deg) with unprecedented sensitivity in both flux density (1sigma ~ 60 uJy/beam) and the capability of detecting emission with angular scales in the range from 1" to the largest radio structures in the Galaxy. I will present, for the first time, the complete GLOSTAR-VLA D-configuration radio source catalog of the Galactic disk. The catalog consist of ~13000 radio sources, including the spectral indices to many of them by complementing our results with those from the THOR survey at 1.4 GHz. We identify ~1000 HII region candidates, of which ~400 are new. The mean value of spectral indices of 225 HII regions is +0.14 +- 0.02, consistent with most of them being produced by optically thin thermal radio emission. These results will be fundamental to support new tools for future Galactic surveys and studies of the view of the Milky Way.

Directly imaging the Circumgalactic Medium with the Dragonfly Spectral Line Mapper

Seery Chen[1], Dr Deborah Lokhorst[2], Imad Pasha[3], Prof Roberto Abraham[1], Prof Pieter van Dokkum[3]

[1]University of Toronto. [2]NRC Herzberg Astronomy and Astrophysics Research Centre. [3]Yale University

Abstract

The Dragonfly Spectral Line Mapper (DSLM) is a new instrument designed to directly image the circumgalactic medium of local galaxies in H-alpha, [NII], and [OIII] emission. With a wide field of view encompassing the virial radius of most nearby galaxies, and reaching unprecedently low surface brightness limits, DSLM breaks ground on a new era of ultra low surface brightness emission line imaging. Data from DSLM will provide a "big picture" point of view to investigate the morphology of the diffuse ionized circumgalactic medium around individual galaxies, extending the study of the CGM in emission down from the higher redshifts covered by IFUs such as KCWI and MUSE to the local universe. DSLM surveys have started in January 2024 and expect science data on the first targets to be ready in March 2024. Here we give a brief overview of the DSLM instrument and survey design, and present preliminary data from our commissioning phase including some of the deepest wide field emission line imaging to date, on galaxies NGC 3079 and NGC 891.

Comparative Spectroscopic Analysis of Very Massive Stars in Metal-rich and Metal-poor Star Clusters: Insights from HST FUV Observations

Dooseok Jung[1], Senior Research Astronomer Linda Smith[2], Distinguished Professor Daniela Calzetti[1], Research Assistant Professor Mark Heyer[1], Professor Min Yun[1], Associate Professor Katherine Whitaker[1]

[1]University of Massachusetts Amherst. [2]Space Telescope Science Institute

Abstract

We perform a spectroscopic investigation of very massive stars (VMSs), exceeding 100 solar masses, within young and compact star clusters situated in both a nearby metal-rich star-forming spiral galaxy (greater than 0.5 solar metallicity) and metal-poor (less than 0.3 solar metallicity) star-bursting irregular dwarf galaxies. Our study utilizes far-ultraviolet (FUV) spectra acquired from the Hubble/COS and Hubble/STIS instruments for star clusters in M101, NGC 1140 and NGC 4449. Physical parameters are derived employing SESAMME, a recently released spectral fitting tool enabling Simultaneous Estimates of Star-cluster Age, Metallicity, Mass, and Extinction, incorporating BPASS and Starburst99 spectral population synthesis models. A comparison of the FUV spectral features of star clusters in dwarf galaxies (NGC 1140 and NGC 4449) with those in M101 suggests the presence of VMSs, characterized by robust emission line detections of He II and N IV, alongside conspicuous O V absorption line detections attributed to VMSs' stellar winds. These observations imply an exceptionally young upper age limit (less than 2 Myr) for the lifetimes of VMSs. We present the characteristics of these young, massive, and compact star clusters, emphasizing their heightened star-forming activities and broad range of metallicities, while discussing their potential as analogs for compact sources observed at high redshift, such as Green Pea galaxies, within pristine environments.

Spatially resolved extinction in NGC 3324 from star counts in JWST images

Dr. Alejandro Raga[1], Jorge Castorena[1], Dr. Sylvie Cabrit[2], Dr. Mayra Lebron[3], Dr. Carmen Pantoja[3], Dr. Hector Arce[4], Dr. Paul Goldsmith[5]

[1]Instituto de Ciencias Nucleares, UNAM. [2]Observatoire de Paris, PSL Université, Sorbonne Université. [3]University of Puerto Rico - Río Piedras Campus. [4]Yale University. [5]Jet Propulsion Laboratory, California Institute of Technology, USA

Abstract

We have calculated the spatially resolved extinction from star counts using the publicly available JWST Early Release Observations of the NGC 3324 nebula. The large number of point sources observed in these images allows us to obtain extinction maps with a relatively high, ~ 30'' angular resolution (corresponding to ~ 0.3 pc at a distance of ~ 2.2 kpc to NGC 3324). We have also used the colors of the observed point sources to determine their extinction, through comparison with synthetic colors in the JWST filters for main-sequence stars, and find results that are remarkably consistent with the ones obtained from star counts. Furthermore, the extinction, at 0.9 - 3.35 μm, follows closely the average galactic extinction curve with $A_V = 6.5$ mag. We find that the molecular region of the observed field has two dense clouds, each with a $M = 95 \pm 7\ M_{Sun}$ mass within projected areas of ~1 pc^2. Therefore, these clouds are likely to be localized low mass star formation regions.

Double-Lensed Emission of PSR B0834+06

Lydia Guertin[1,2], Dr. Daniel Baker[2], Dr. Ue-Li Pen[2,3,4], Dr. Daniel Stinebring[5]

[1]Haverford College, PA, USA. [2]Academia Sinica Institute of Astronomy and Astrophysics, Taipei, Taiwan, ROC. [3]Canadian Institute for Theoretical Astrophysics, University of Toronto, ON, Canada. [4]Department of Physics, University of Toronto, ON, Canada. [5]Department of Physics and Astronomy, Oberlin College, OH, USA

Abstract

Using archival Arecibo observations of PSR B0834+06, we identify and track the motion of a doubly-lensed group of images in the two-dimensional Fourier transform of the dynamic spectrum. Following basic scintillometry techniques, we use the θ-θ transform to phase-connect frequency and time chunks of each observation, allowing us to extract parameters of the physical screen causing the double-lensing of the pulsar, including its distance and orientation relative to the line of sight. By tracing the group of doubly-lensed images, we are able to determine the geometry of the lensing event and compare this event to the literature of proposed mechanisms. Interestingly, we find evidence of asymmetric arcs in the secondary spectra, which suggest lensing dominated by a second screen during a period of crossing along the line of sight unseen in previous scintillation studies.

Constraints on the properties of νMSM dark matter using the satellite galaxies of the Milky Way

Dr Oliver Newton[1], Dr Mark Lovell[2], Prof. Carlos Frenk[2], Prof. Adrian Jenkins[2], Dr John Helly[2], Prof. Shaun Cole[2], Dr Andrew Benson[3]

[1]Center for Theoretical Physics, Polish Academy of Sciences. [2]Institute for Computational Cosmology, Durham University, UK. [3]Carnegie Observatories, California, USA

Abstract

Low-mass galaxies are powerful tools with which to investigate departures from the standard cosmological paradigm in models that suppress the abundance of small dark matter substructures. One of the simplest metrics that can be used to compare different models is the abundance of satellite galaxies in the Milky Way. Viable dark matter models must produce enough substructure to host the observed number of Galactic satellites. Here, we scrutinize the predictions of the neutrino Minimal Standard Model (νMSM), a well-motivated extension of the Standard Model of particle physics in which the production of sterile neutrino dark matter is resonantly enhanced by lepton asymmetry in the primordial plasma. This enables the model to evade bounds associated with non-resonantly produced dark matter. Independently of assumptions about galaxy formation physics we rule out, with at least 95 per cent confidence, all parametrizations of the νMSM with dark matter particle masses, $M_s \leq 1$ keV, independently of other model parameters and of the Milky Way halo mass. Incorporating physically motivated prescriptions of baryonic processes and modelling the effects of reionization strengthens our constraints and we exclude all models with $M_s \leq 3$ keV. Unlike other literature, our fiducial constraints do not rule out the putative 3.55 keV X-ray line hinted at by observations of dark matter-dominated systems, if it is indeed produced by the decay of a sterile neutrino. We find that the constraints from satellite counts are substantially weaker than the limits reported from X-ray non-detections.

[8]Technical University of Munich, School of Engineering and Design, Department of Aerospace and Geodesy, Germany

Abstract

Globular clusters are sensitive tracers of galaxy assembly histories. We examine how the mass ratio of major mergers affects the formation and disruption of globular clusters in a simulated present-day L^* galaxy. Starting from a zoom-in simulation of a system that experienced major mergers at z=1.7 and z = 0.77, we employ the genetic modification technique to enhance the mass ratio of the latter merger by a factor of two (enhanced case) or prevent it from occurring (suppressed case). The formation and evolution of star clusters is implemented using the MOSAICS model in the subgrid of the EAGLE hydrodynamics scheme. Our simulations reveal that most of the globular cluster system forms during the first merger and that most of the subsequent evolution is affected mainly by the characteristics of this merger. Late-time mergers, if they take place, play a minor role by prolonging the galaxy's phase of net star cluster formation by up to 1 Gyr after the coalescence of the remnant. At z=0 this manifests as an overabundance of massive star clusters in the enhanced case compared with the unmodified assembly history, while the suppressed case has more low-mass clusters. Two commonly used observational metrics to characterize the richness of globular cluster systems are the specific frequency and the specific mass. At z=0 we find that the latter is stratified as a function of the mass ratio of the target merger; however, the specific frequency is not. This feature could prove useful to elucidate the assembly histories of galaxies from present-day observations.

Modeling cosmic ray electron spectra and synchrotron emission in the multiphase ISM

Nora Linzer, Lucia Armillotta, Eve Ostriker, Eliot Quataert

Department of Astrophysical Sciences, Princeton University, Princeton, NJ, USA

Abstract

We model the energy dependent transport and spectral evolution of 1-100 GeV cosmic ray electrons (CREs) in the TIGRESS MHD simulations of the multiphase ISM. This implementation of CR transport combines advection, streaming, and diffusion, with a diffusion coefficient determined by the local gas and CR properties based on a balance between the CR streaming instability and wave damping rather than a value derived from observation. Additionally, we include loss mechanisms important for the evolution of the CRE spectrum such as synchrotron, inverse Compton, and bremsstrahlung losses. We post-process a TIGRESS model representing the local ISM and find the resulting CRE spectrum to be consistent with direct observations. From these models, we produce synthetic maps of radio synchrotron emission and find the observationally estimated value of the CRE spectral index to match closely the true spectrum. These models enable us to test other predictions made with synchrotron observations such as the equipartition model of magnetic fields.

The role of metals from molecular clouds to galactic discs

Piyush Sharda

Leiden Observatory, Leiden University, Netherlands

Abstract

From the time the first stars formed to the present-day, metals have witnessed the assembly of structure in the Universe in great detail. Although metals only form in stars and stellar remnants, they are ubiquitously present everywhere -- from planetary cores to the intergalactic medium. However, we still do not understand how metals are effectively dispersed throughout the Universe, and the various roles they play in shaping galaxies. In this talk, I will present a multi scale approach to study the role of metals in galaxy evolution, from molecular clouds to galactic discs. On smaller scales, I will focus on physical processes that shape up the initial mass function (IMF, with a particular emphasis on metal-free and metal-poor environments) that directly set the integrated yield of metals in the first and early galaxies. I will discuss results from high resolution simulations that study the impact of turbulence, radiation, and magnetic fields on the primordial IMF, and describe analytical models of dusty molecular clouds that explain the transition in the IMF as the metal abundance grows over cosmic time. On larger scales, the talk will cover the physics of gas-phase metal distribution in galaxies. Using a combination of spatially-resolved gas-phase metallicity measurements and novel semi-analytical models, I will present recent results that advance our understanding of metallicity gradients in (late type) galaxies. In particular, I will show how self-consistently incorporating metal dynamics into galaxy evolution models is key to explaining the observed trends in metallicity gradients with galaxy mass, metallicity, and kinematics. I will end by highlighting how such a multi-scale approach is necessary to study the physics of galaxy evolution at cosmic dawn that is now within the reach of JWST.

Zooming in on the Chemistry of Planet Formation: The ALMA View of Molecular Gas inProtoplanetary Disks

Dr Charles J. Law

University of Virginia

Abstract

Planets form and obtain their compositions in gas-rich disks around young stars. The molecular gas and associated chemistry are directly tied to the resulting exoplanet architectures, including what types of planets form, their atmospheres, and potential habitability. Thanks to its high angular resolution and sensitivity, ALMA has transformed our understanding of the chemical and physical structure of planet-forming disks. Here, I first present ALMA observations of over 50 molecular lines at 10 au scales in five protoplanetary disks, as part of the Molecules with ALMA at Planet-forming Scales (MAPS) Large Program. These observations represent the most comprehensive disk chemistry survey conducted at these scales and allowed for a detailed mapping of the radial and vertical gas structure. Chemical substructures in the form of rings and gaps are ubiquitous and extremely varied in their properties across the MAPS disks, which suggests that planets form in diverse chemical environments. Not only do planets form in disks, but they locally alter disk chemistry. Using ALMA archival data, I also identified several compelling planet-induced chemical signatures in the giant-planet-hosting HD 169142 disk, including the first disk detection of shock- tracing molecule SiS. This discovery shows that observations of shock-tracing molecules provide a novel approach to the detection and characterization of young, embedded planets. Taken together, these results demonstrate the utility of high-resolution ALMA observations of molecular lines in disks, and going forward, we aim to expand this approach to larger and more representative samples to obtain statistical constraints on the chemistry of planet formation.

[4]City University of New York. [5]Mount Saint Vincent University, Saint Mary's University, Université Laval, Dalhousie University

Abstract

Diffuse interstellar bands remain an outstanding challenge as their carriers are either unknown or contested, and the impact of the ambient environment on the abundances and spectral profiles is complex and poorly constrained. Here, the spiral arm location of a subset of stars in the APO DIB catalog are determined, with the final aim of assessing how that may influence Pearson correlations used to identify families of interrelated lines tied to a single molecular source. Progress is likewise conveyed with respect to quantum chemistry calculations being carried out to estimate vibrational and electronic spectra for potential molecular sources, which may be compared to observations.

L-Galaxies: Debugging galaxy evolution across cosmic epochs through galaxy scaling relations

Akash Vani[1], Mohammadreza Ayromlou[2], Guinevere Kauffmann[1], Volker Springel[1]

[1]Max Planck Institute for Astrophysics, Karl-Schwarzschild-Str. 1, 85741 Garching bei München, Germany. [2]Universität Heidelberg, Zentrum für Astronomie, Institut für theoretische Astrophysik, Albert-Ueberle-Str. 2, 69120 Heidelberg, Germany

Abstract

L-Galaxies is a semi-analytical galaxy formation model that employs a suit of physical prescriptions to model baryonic physics on top of dark matter halo merger trees. This study presents an extensive comparison between the L-Galaxies simulation and several observations from different fields, including CANDELS, COSMOS, JADES, and CEERS. Our investigation spans across a large redshift range ($0 \lesssim z \lesssim 10$) and a broad mass spectrum ($7 \lesssim \log M_* \lesssim 12$).

In particular, we examine the three most recent versions of L-Galaxies (Henriques+15,20, Ayromlou+21), which were independently calibrated using an MCMC approach based on low redshift observations of the stellar mass function and the quiescent galaxy fraction. In this work, we study the redshift evolution of different galaxy scaling relations provided by different recent publications, including the main sequence of star-forming galaxies, galaxy stellar mass function, mass-size relation, central surface mass density relation, and the cosmic star formation rate density. These relations are examined for both star-forming galaxies (SFGs) and quenched galaxies (QGs).

Our analysis shows that the majority of the simulation predictions are in qualitative agreement up to $z \sim 2$. However, several tensions persist at both low and high redshift, underscoring the need for future refinements in the physical prescriptions of L-Galaxies. A more robust suppression of star formation for massive, low redshift galaxies is required. Other tensions underscore the necessity for improved quenching mechanisms, particularly AGN feedback at high redshifts for all galaxies.

Probing the cosmic reionisation with the Hydrogen Epoch of Reionization Array (HERA).

Mr Ntsikelelo Charles

North West University

Abstract

The 21 cm transition from neutral Hydrogen promises to be the best observational probe of the Epoch of Reionisation (EoR). It has driven the construction of the new generation of low-frequency radio interferometric arrays, including the Hydrogen Epoch of Reionization Array(HERA). The main difficulty in measuring the 21 cm signal is the presence of bright foregrounds that require very accurate interferometric calibration. However, the non-smooth instrumental response of the antenna as a result of mutual coupling complicates the calibration process by introducing non-smooth calibration errors. Additionally, incomplete sky models are typically used in calibration due to the limited depth and resolution of current source catalogues. Combined with the instrumental response, the use of incomplete sky models during calibration can result in non-smooth calibration errors. Thus compromising the detection of the 21 cm signal. In this work, we explore the use of fringe rate filters (Parsons et al., 2016) as a means to mitigate calibration errors resulting from the effects of mutual coupling and the use of an incomplete sky model during calibration. We found that the use simple notch filters significantly improves the calibration by minimising calibration errors resulting from effects of mutual coupling and the use of an incomplete sky models during calibration.

1-Point statistical Detection of kSZ Signal in ACTPol DR4 Maps

Dr. Mthokozisi Mdlalose

University of KwaZulu-Natal

Abstract

Measurements of galaxy cluster kinematics have the potential to provide constraints in dark modeling and also provide a unique constraint on baryon density in an intracluster medium. This work uses a 1-point statistical detection of the kSZ signal in ACTPol DR4 maps. To obtain the kSZ signal, we perform aperture photometry on BOSS NORTH and Deep 56 regions of ACTPol DR4 using galaxy cluster positions from DESI Legacy Survey Imager Data Release 8. With the kSZ signal, we estimate the velocity dispersion of the galaxy cluster.

Searching for high-redshift radio galaxies with the MeerKAT Galaxy Cluster Legacy Survey

Mr Vasco Cossa

Rhodes University

Abstract

We present the results of a search for high-redshift radio galaxies (HzRGs) within 20 fields of the MeerKAT Galaxy Cluster Legacy Survey's first data release. These fields are distinguished by their robust dynamic range and comprehensive coverage in the optical and infrared spectrum through the Dark Energy Camera Legacy Survey and the All-Sky Wide Infrared Survey Explorer surveys. HzRGs, potentially precursors to local elliptical galaxies, offer a unique lens for exploring diverse astrophysical phenomena, including large-scale cosmic structures, galaxy evolution, and the epoch of reionization. Employing adept multiwavelength cross-matching techniques, the candidate pool has been meticulously refined, followed by harnessing in-band spectral indices extracted from MeerKAT data. MeerKAT's extreme sensitivity has allowed us to detect a large number of new HzRG candidates, at radio luminosities an order of magnitude lower than other studies, effectively positioning them for subsequent spectroscopic analysis.

The properties of radio relics and the connection with radio halos in galaxy clusters and their correlation with non-thermal phenomena at multi-frequency

Prof Claudio Paulo[1], Dr Paolo Marchegiane[2], Prof Sergio Colafrancesco[3]

[1]Universidade Eduardo Mondlane, Faculdade de Ciências, Departamento de Física, Grupo de Astrofísica, Ciências Espaciais e Inteligência Artificial. [2]INAF-Osservatorio Astronomico di Cagliari, Via della Scienza 5, I-09047 Selargius (CA), Italy. [3]deceased; formerly at School of Physics, University of the Witwatersrand, Private Bag 3, WITS-2050, Johannesburg, South Africa

Abstract

We present an investigation of the properties of radio relics (RRs), one type of diffuse emission located at the outskirts of some Galaxy Clusters (GCs), and a search for information about the origin of non-thermal processes taking place in the cluster atmospheres. We adopt a new approach to constrain models for the origin of RRs according to the following steps: i) Instead of working on a single relic, we worked on a large sample of RRs, by performing the compilation of one of the largest reference cluster relic sample (77 relics) available; ii) We perform a study of statistical properties of RRs and the hosting clusters by evaluating the relationship between the radio power of relics at 1.4 GHz and: radio halos power, cluster X-rays bolometric luminosity, integrated Compton parameter, cooling time, and Mach number of the shock associated to the relic; iii) We perform morphological analysis of the connection between RRs and the population of fossil particles coming from radio galaxies jets and lobes in the cluster. The results obtained show that relics know about halos because they scale together in their radio powers, galaxy activity in the cluster centre, and cluster properties like X-ray luminosity and Integrated Compton parameter. Examination of relics in other clusters, as well as optical/infrared spectroscopic studies of candidate radio galaxies as possible origins of the relics, and deep radio studies of their jets and lobes, will be necessary to derive solid results.

Dark matter, dynamics, and disequilibria in the Milky Way

Arpit Arora, Prof. Robyn Sanderson

University of Pennsylvania

Abstract

The nature of DM manifests at galactic scales, where we impose constraints by modeling star and gas orbits, typically in the high-density central regions of the MW and its satellites. In these regions, the DM physics is sub-dominant to baryonic processes. Additionally, modeling techniques often rely on assuming some symmetry and/or equilibrium for the MW halo. However, the MW's halo is asymmetric due to accretion along filamentary structures and in disequilibrium, courtesy of the in-falling LMC in the outer halo and the Sagittarius dwarf in the disc. In this talk, I will discuss; 1) a novel technique to model time-evolving MW potential, capturing deformations induced by in-falling massive satellites using Basis Function Expansions; 2) an innovative application of this potential model to understand anisotropic boosts in subhalo-stream interactions driven by the LMC. Finally, I will explore the prospects of constraining DM by out-of-equilibrium modeling in the outermost, DM-dominant regions of the MW.

Abstract

An extensive analysis of observed spheroidal dwarf satellites of the Andromeda galaxy was conducted to provide a comprehensive catalog of long-period variable (LPV) stars. The study is part of an optical monitoring survey to observe 55 dwarf galaxies and four globular clusters within the Local Group. The dwarfs were observed using the wide field camera (WFC) of the 2.5 meter Isaac Newton Telescope (INT). These observations were conducted through near-infrared (i Sloan) and optical (V Harris) bands at nine epochs. Our focus is on detecting asymptotic giant branch (AGB) stars when their magnitude amplitude becomes higher than 0.2 mag to track dwarf evolution. In dwarf galaxies, LPV stars provide powerful tools for reconstructing the SFH. LPV stars are suitable for study due to the relation between their birth mass and luminosity at the end of their evolution. Star formation scenarios could also be studied by comparing the age gradient of variable stars between two half-light radii. This study also provides estimates of satellite characteristics such as the half-light radius, the RGB-tip, the distance modulus, the quenching time, and the total stellar mass. Our work is extended by estimating the mass-loss rates of detectable LPVs to produce dust maps for each dwarf. A combination of ground-based observations and space-based telescopes was used to simulate the spectral energy distribution (SED) for LPVs based on observations in the optical to mid- infrared bands. It is also possible to estimate the re-ignition time for SFH by calculating the total mass return of LPVs.

[3]Department of Cybernetics and Artificial Intelligence, Faculty of Electrical Engineering and Informatics, Technical University of Kosice, 042 00 Košice, Slovakia

Abstract

The advent of large astronomical surveys calls for the application of machine learning methods to process large amounts of data. For this purpose, we developed a cutting-edge deep learning technique that can accurately detect spiral, edge-on galaxies in astronomical images, which can then be used for analysis. We will describe the characteristics of the galaxies in our sample and discuss potential biases and caveats. We will also present a novel application of this algorithm: detection of galactic warps. The galactic warp, i.e. the twisting of the outer edges of the galactic disc, is a well-known phenomenon occurring in most spiral galaxies, including the Milky Way. Despite the fact that we know hundreds of warped galaxies of different shapes and sizes, it is still not clear how the warp is created. We will demonstrate how our algorithm can yield a deeper statistical analysis that will enable us to make connections between the different warps and understand their environmental dependencies.

Abstract

Galaxy mergers play a crucial role in galaxy evolution, yet their relationship with the local environment is not fully understood. However, it is well-established that galaxy properties are correlated with their local environment. In this talk, I will present our findings about whether galaxy mergers prefer to exist in the denser or less dense regions of the large-scale structure. Our approach involves quantifying the spatial clustering of mergers and non-mergers by utilising the galaxy two-point correlation function. We also explore the environmental dependence of a galaxy's likelihood of undergoing a merger event using the marked correlation function. We use these statistical tools on a set of mergers and non-mergers identified from Galaxy and Mass Assembly survey. The classification was done using a Convolutional Neural Network. We find a stronger spatial clustering of non-mergers and an anti-correlation between the merger likelihood of a galaxy and the local environment. These results imply less preference of galaxy merger occurrences in the extremely dense environments.

The SPARC galaxies and the External Field Effect of MOND

The SPARC galaxies and the External Field Effect of MOND Hamed Fazel Modarres

Institute for Advanced Studies in Basic Sciences (IASBS)

Abstract

In any theory of nonlinear gravitational dynamics such as MOND, the principle of strong equivalence is violated, while Newtonian dynamics is linear and obeys the principle of strong equivalence. As a result, the gravitational dynamics in the system remain under the influence of the external gravitational field in which the system is immersed. This is a good option for testing the MOND dynamics, which is known as the external gravitational field effect (EFE). Of course, most researchers do not consider the external field's effect in studying the spiral galaxy curve. In this study, we theorize the periodic curve of galaxies from the SPARC data set by considering the external gravitational field's effect and comparing the results with observational data.
In the second phase of this project, we have investigated the impact of the gravitational field effect of the neighboring galaxies of 157 SPARC galaxies (Spitzer photometry and precise rotation curves) on the rotation curve of these galaxies in the MOND (Modified Newtonian dynamics) regime. we found all SPARC galaxies and their neighbors' distances and their stellar and gas mass by astronomical catalogs and surveys like (EDD, SDSS, NED, SIMBAD, and ALFALFA). Then we calculated the imposed external acceleration of neighbor galaxies to each SPRAC galaxies and compared it with first-phase results.

MeerKAT Observations of the Abell 141 Galaxy Cluster

Ms Savannah Stanbury

Rhodes University

Abstract

Galaxy clusters are one of the largest, gravitationally bound structures in the universe, hosting a hot, tenuous gas that permeates their volume, known as the intracluster medium. A fraction of the intracluster medium is composed of relativistic electrons that, when accelerated in magnetic fields, radiate synchrotron emission. Synchrotron emission occurs on scales ranging between individual galaxies to ~Mpc scales and beyond, with two examples of radio emission observed on Mpc scales, "bridging" between cluster pairs. A possible third system to host radio emission on such large scales is the Abell 141 (hereafter, A141) cluster, a system composed of two subclusters, where X-ray emission has been seen in the connecting region. Radio observations at 150 MHz and 943 MHz detected diffuse emission from the two systems, although the limited angular resolution prevented a detailed picture of the system.

In this thesis, we present observations at 1.28 GHz of the A141 system, taken with the MeerKAT telescope, with the aim to further characterize its diffuse radio emission. We obtain images where we detect diffuse radio emission extending over 0.9 Mpc.

The radio surface brightness peaks at the location of the Northern subcluster, and we can clearly see radio emission in the region between the two subclusters, though it does not closely follow the X-ray morphology.

A141 remains a somewhat unique system. We confirmed the spectral index of the integrated radio emission to somewhat disfavour the current most likely scenario where particles are accelerated by turbulence in the early merger state.

Spectral Study of Two ACT Clusters Using SKA Pathfinders/Precursors

Ms Mikaela Webber, Dr Kenda Knowles, Professor Oleg Smirnov

Rhodes University

Abstract

Galaxy clusters are complex environments used to study cosmology and astrophysical phenomena. Magnetic fields in clusters and a cluster's non-thermal physics can be probed through observations of steep-spectrum, diffuse radio emission such as radio halos. Understanding a halos' spectral behaviour and morphology is critical for probing the underlying electron population and the formation mechanisms involved. In this project, we use data from SKA pathfinder and precursor instruments as well as archival multi-wavelength data in order to study the radio environment of two clusters detected through their Sunyaev-Zel'dovich signal with the Atacama Cosmology Telescope, both of which have candidate detections of a diffuse radio halo.

HI Asymmetries and Deficiencies in ALFALFA

Ms Reshoketswe Thobejane

University of the Western Cape

Abstract

In this work, we aim to use HI line data from the Arecibo Legacy Fast ALFA(ALFALFA) survey to study the prevalence of HI spectral asymmetries in the context of galaxy environment. From the full ALFALFA sample, we define as 'merger candidates' , those galaxies that have a neighbour within 25 kpc and 750 $km.s^{-1}$. A sample of well-isolated galaxies is also procured. Here, for each sample, distributions of their defining observational characteristics are presented. The goal is to quantify the asymmetries in these two galaxy samples in order to generate quantifiable evidence of the environment-induced effects.

A Detailed Study of Dwarf Galaxies in the Core of the Coma Cluster

Prof Syed Najamul Hasan, Dr Priya Shah

Maulana Azad National Urdu University, Hyderabad, India

Abstract

In an earlier paper, we determined the morphological types of galaxies in the Coma Cluster using data from the HST/ACS Coma Cluster treasury survey.

We found that of the 132 members, 51 are non dwarfs and 81 are dwarfs.

In this paper, we determine the morphological types of these dwarf galaxies and make a \replaced{detailed}{deeper} study of their properties. Using GALFIT, we determine the structural properties of our sample and with spectroscopic redshifts, we determined memberships and distances to identify dwarfs. A visual examination of the residual images reveals that our sample of 78 dwarf galaxies comprises of: dwarf lenticular (\textit{dS0}) 22\%, dwarf Elliptical (dE) 69\%, dwarf spirals (\textit{dSp}) 4\%, dwarf ring (\textit{dring}) 1\%, dwarf barred spirals (\textit{dSBp}) 3\% and dwarf irregular (\textit{dIrr}) 1\% galaxies. We find that the bulge-disk decomposition (Sérsic + exponential) fits are good only for the \textit{dS0} galaxies. The remainder of the sample gives good fits only for single Sérsic fits. The Colour Magnitude Relation (CMR) shows that the dEs are redder and fainter than the rest of the sample (except one $dIrr$ galaxy). The Kormendy relation reveals that dE galaxies have lower surface brightness than the rest of the sample. Our research leads us to the conclusion that dwarf galaxies appear to have a different formation and evolution process than non-dwarf galaxies.

Enabling New Discoveries with Machine Learning

Dr Michelle Lochner

University of the Western Cape. South African Radio Astronomy Observatory

Abstract

The next generation of telescopes such as the SKA and the Vera C. Rubin Observatory will produce enormous data sets, far too large for traditional analysis techniques. Machine learning has proven invaluable in handling massive data volumes and automating many tasks traditionally done by human scientists. In this talk, I will explore the use of machine learning for automating the discovery and follow-up of interesting astronomical phenomena, both in the image and time domains. I will share an exciting recent MeerKAT discovery made with machine learning and discuss how the human-machine interface will play a critical role in maximising scientific discovery with automated tools.

Probing the Evolution of Quasars: Insights from Multi-Wavelength Observations

Marina Arnaudova, Daniel Smith, Martin Hardcastle

University of Hertfordshire

Abstract

AGN play a crucial role in shaping galaxies and the multi-phase medium, highlighting the significance of studying quasars—the most luminous manifestations of these objects—across cosmic time. Such sources are typically divided into radio-loud (RL) and radio-quiet (RQ) categories, which raises the question of whether these classes represent distinct populations or different evolutionary stages of a single one. To provide an answer, we combined 144 MHz radio observations from LoTSS DR2 with spectroscopic data from SDSS DR14Q to create the largest sample of uniformly-selected, spectroscopically-confirmed RL and RQ quasars at $0.6<z<3.4$ across 5634 deg^2. To investigate their properties, we developed a new spectral stacking algorithm and used it to create high-resolution composite spectra for each radio class, matched in redshift and absolute i-band magnitude. We found that RL quasars have a redder continuum and enhanced [OII] emission compared to their RQ counterparts. These results persist when additionally matching in black hole mass, suggesting that this parameter is not the defining factor in making a QSO radio-loud. In addition, these features do not gradually vary as a function of radio-loudness but are maintained even when probing deeper into the RQ population, indicating that a clear-cut division in radio-loudness is not apparent. We further show that RL QSOs exhibit a significant excess of star-formation relative to RQ quasars up to at least $z=1.9$. Given our findings, we explore potential explanations and discuss how advancements in future instrumentation and survey methodologies could deepen our understanding of the subject.

Exploring the Impact of Galaxy Interactions: New Insights from Stephan's Quintet

Marina Arnaudova[1], Soumyadeep Das[1], Daniel Smith[1], Martin Hardcastle[1], Nina Hatch[2], Scott Trager[3]

[1]University of Hertfordshire. [2]University of Nottingham. [3]University of Groningen

Abstract

Galaxy mergers and interactions are a cornerstone of our understanding of how galaxies form, but their precise role in driving galaxy evolution across cosmic time is still widely debated. Compact galaxy groups at low-redshift, such as Stephan's Quintet (SQ), however, give us the opportunity to study such processes in more detail. This galaxy group is at a unique dynamical stage where we are able to observe manifestations of both past and present interactions by examining its most distinguished feature: the large-scale shock front. This system contains a wealth of multi-wavelength information including radio observations from the LOFAR Two-metre Sky Survey (LoTSS) and targeted observations with the Very Large Array (VLA). Recently, the next generation spectroscopic facility on the 4.2m William Herschel telescope in La Palma - WEAVE, has contributed to this wealth of information with its first panoramic optical integral field unit (LIFU) observation. By harnessing this instrument's large field of view and high spectral resolution (R=10 000), we are able to study the physical characteristics of the ionized gas by performing robust spectral fitting of complex line profiles on an individual spaxel of 2.6 arcsec basis across the area of 90x78 arcsec^2. This combined with radio spectral index maps (between 144MHz, 1.7GHz and 4.8GHz) allows us to determine the ionisation mechanism, age, and thermodynamics of the particles populating the structure, and thus shed new light on the interplay between galaxy-galaxy and galaxy-intergalactic-medium interactions.

Galaxy evolution through the eyes of resolved, multi-wavelength star formation observations: tracing the chemical and accretion history in nearby galaxies

Dr Kathryn Grasha

Dr. Kathryn Grasha is an observational astronomer at the Research School of Astronomy and Astrophysics at the Australian National University. Her research sheds light on the physics that governs how galaxies transform and evolve by tracing how oxygen atoms we breathe and the carbon we are made of formed across cosmic time.

Abstract

Measuring the chemical history of galaxies is critical to understand how galaxies form and evolve. This is usually done through observations of emission lines from ionized nebulae, where their bright emission lines enable the measurement of physical properties, such as the gas-phase metallicity, across galaxy disks and in distant galaxies. In this talk I will present the newest state-of-the-art stellar evolution models based on the latest models of chemistry elements in the early universe to the determine chemical abundance patterns, pressure, star-formation rates, heavy element enrichment, and the production and escape of ionizing radiation from the first galaxies. Using these self-consistent chemistry and stellar population synthesis models, we use the observed stellar mass and detailed metallicity gradients to identify a best-fit to our galaxies within the IllustrisTNG cosmological simulations to characterize the likely chemical and accretion history. Our work suggests that the combination of cosmological simulations and high spatial resolution metallicity gradient observations can provide an archeological probe of the gas accretion and merger history of face-on spiral galaxies. With this, we are able to disentangle the different physical mechanisms regulate gas inflows and outflows and the resulting effects on the star formation activity. This project will exploit the next generation spectroscopy with the James Webb Space Telescope to make fundamental new measurements of the formation of stars in the first galaxies, linking the low and high redshift universes.

Insights into early galaxy evolution models from z>3 massive quiescent galaxies.

Dr Themiya Nanayakkara

Swinburne University of Technology

Abstract

Advancements in near-infrared observational capabilities in the last decade transformed our understanding of early cosmic evolution through the discovery of abundant populations of z>3 massive (M> ~10**10 msol) quiescent galaxies. While photometric techniques have identified possible red galaxies at z~9, JWST/NIRSpec observations have now been able to explore the formation histories of lower redshift galaxies in detail. The earliest indications for temporary quiescence has been found at z~7 with results indicating SFHs of galaxies to be more stochastic than what was expected before. The strong alpha element spectral signatures along with features that are commonly observed in AGB star dominated z~0 massive quiescent galaxies provide us an opportunity to study the detailed chemistry of quiescent systems. Forensic analysis of z~3 massive quiescent galaxies has shown the existence of galaxies that likely have formed ~10**11 msol within the first 500 years of the universe (by z~10) and quenched rapidly through unknown mechanisms. Hydrodynamical simulations are suggesting AGN effects to be the primary driver in abruptly quenching star-formation in galaxies in the early Universe, thus requiring most of observed massive galaxies to harbour prominent broad line AGN. In my talk I will discuss latest advancements in this field, including the formation history of z>3 massive and quiescent galaxies, the role of AGN in forming these systems, and discuss implications this buildup of stellar mass which may have for z>6 star-formation efficiencies and hierarchical galaxy growth scenarios.

Structure growth in $f(Q)$ cosmology

Dr Shambel Akalu[1], Prof Amare Abebe[1], Prof \'{A}lvaro de la Cruz-Dombriz[2]

[1]North-West University. [2]University of Cape Town

Abstract

In this article, we take into account redshift-space distortion measurements to investigate the growth of large-scale structures within the framework of symmetric teleparallel gravity, dubbed $f(Q)$ gravity. After studying the background history of the universe in $f(Q)$ gravity with OHD, SNIa, and OHD+SNIa datasets and constraining the pertinent cosmological parameters Ω_{m}, H_0 together with the exponent n for $f(Q)$ power-law models, we derive the full system of equations governing the linear cosmological perturbations using the $1 + 3$ covariant formalism to obtain both the scalar and the harmonic decomposition. {Usual redshift-space distortions data $f\sigma_8$ have been combined with the recent measurements of the growth rate f and the amplitude of matter fluctuations σ_8 from the VIPERS and SDSS collaborations to find the best-fit cosmological parameters, such as Ω_m, σ_{8} and n. We also provide {the evolution for} density fluctuations in both the long- and short-wavelength modes and in both the matter- and radiation-dominated epochs of the universe. We use Monte Carlo Markov Chain simulations (MCMC) to restrict the best-fit parameter values and determine their statistical significance through the Bayesian selection criteria AIC and BIC to study the background history of the universe and the growth structure by taking into account the viability of the $f(Q)$-gravity model.

The significance of characterizing the sidelobe systematics in 21cm Intensity Mapping experiments: The HIRAX case.

Mr Ajith Sampath[1], Prof Kavilan Moodley[1], Dr Devin Crichton[2]

[1]University of KwaZulu-Natal. [2]ETH - Zurich

Abstract

HIRAX (the **H**ydrogen **I**ntensity and **R**eal-time **A**nalysis e**X**periment) is an intensity mapping experiment under construction at Karoo desert in South Africa. Our experiment aims to detect BAO signatures to tightly constrain the dark energy equation of state parameters. However, all 21cm experiments, including HIRAX, suffer from foreground leakage due to systematics inherent to the instrument. The primary factor causing this effect is the chromaticity of the antenna, i.e., the frequency-dependent structure of the primary beam. In this study, we use the analytical Fourier counterparts of Zernike polynomials to model the CST-simulated HIRAX primary beams and apply them to drone mapping data. Fitting this analytical basis reveals our primary beam's symmetric and asymmetric structures. Apart from fitting models, we also investigate the impact of sidelobe chromaticity in delay space and examine their effects in the calibration stage by reviewing the calibration solutions using different beam models. Furthermore, by comparing the beam-modeling uncertainties with the expected signal and theoretical noise, we dictate how far into the sidelobes HIRAX has to measure and model to detect the HI signal with a high signal-to-noise ratio (SNR). Our study demonstrates the effectiveness of our beam modeling approach in general and provides insights into the implications of sidelobe chromaticity for accurate estimation of the 21 cm power spectrum.

Dark Energy with HIRAX 21cm Intensity Mapping

Prof Kavilan Moodley

University of KwaZulu-Natal

Abstract

Observations of redshifted 21-cm emission from neutral hydrogen over a wide range of radio frequencies allow us to access redshifts that encompass a vast comoving volume, including the era of dark energy. In this talk, I will present the Hydrogen Intensity Mapping and Real time Analysis eXperiment (HIRAX) project, on behalf of the HIRAX collaboration, which is a proposed 21cm intensity mapping experiment operating at 400-800 MHz that will measure the evolution of dark energy over the redshift range z=0.8-2.5 by using the characteristic baryonic acoustic oscillation scale as a standard ruler. The HIRAX radio telescope array will be sited in the radio-quiet Karoo astronomy reserve in South Africa, and will ultimately comprise 1024 dishes, each six metres in diameter, placed in a compact configuration. I will discuss the design and project status of HIRAX, its scientific prospects and engineering challenges. This includes dark energy forecasts and prospects for interesting cosmological constraints from cross-correlations of HIRAX data with other large-area cosmological surveys in the southern sky. HIRAX will also discover a large number of pulsars and transients, including fast radio bursts (FRBs). I will describe our programme to localise these FRBs using HIRAX outriggers in African partner countries.

Simba-C: An updated chemical enrichment model in Simba for galactic and intragroup/cluster chemical evolution

Mr Renier Hough[1], Prof. Ilani Loubser[1], Prof. Arif Babul[2], Prof. Romeel Davé[3]

[1]North-West University, South Africa. [2]University of Victoria, Canada. [3]University of Edinburgh, Scotland, UK

Abstract

We introduce a new chemical enrichment and stellar feedback model in the Simba simulation, resulting in the Simba-C simulation, a precursor to the Kiara legacy simulation. Based on the state-of-the-art chemical evolution model of Kobayashi et al. 2007, Simba-C tracks 32 elements from H → Ge, as well as removing Simba's instantaneous recycling approximation by treating each star particle as an evolving stellar population. Furthermore, we make some minor improvements to Simba's base feedback models, such as reducing the strength of the active galactic nuclei feedback. Simba-C provides significant improvements on key diagnostics such as the knee of the z = 0 galaxy stellar mass function (i.e., the intermediate mass range), as well as providing a better match to recent observations of the gas/stellar mass-metallicity relations at z = 0, 2. By not assuming instantaneous recycling, Simba-C provides a better match to galactic abundance ratio measures such as [O/Fe] and [N/O]. Therefore, our new model allows for much more accurate galactic chemical evolution tracking through cosmic time in the simulation. We also demonstrate the impact of these newly created metals on the global scaling relations of various X-ray properties (luminosity, temperature, mass, entropy, etc.) on different large-scale environments such as groups and clusters, using both a theoretical and an observational approach.

Exploring the correlations between galaxy properties and environment in the cosmic web using marked statistics

Dr. Unnikrishnan Sureshkumar[1,2], Dr. Anna Durkalec[3], Prof. Agnieszka Pollo[3,2]

[1]Wits Centre for Astrophysics, School of Physics, University of the Witwatersrand, Johannesburg, South Africa. [2]Astronomical Observatory of the Jagiellonian University, Krakow, Poland. [3]National Centre for Nuclear Research, Warsaw, Poland

Abstract

Various galaxy properties such as luminosity, stellar mass, star formation rate and so on are known to be significantly correlated with the local environment of the galaxies. These correlations arise from the environmental dependence of their dark matter halo properties. Studies on such environmental correlations are crucial for better understanding of galaxy evolution. These studies are generally done using local density measurements defined at a particular separation scale around the galaxies. However, it is essential to study environmental correlations on a wide range of scales. This approach helps in the investigation of environmental effects that are prevalent at different scales as well as minimising the impact of the chosen scale for density estimation. In this talk, I will show how marked correlation functions are efficient in tracing the environmental correlations of various galaxy properties simultaneously as a function of the scale. I will present the results from our studies that investigated how luminosities in optical to mid-IR bands, stellar mass, and star formation rate are correlated with the local environment. Additionally, I will show how the marked correlation function is advantageous over traditional two-point correlation functions to explore the environmental dependence of galaxy mergers. Our analysis utilises stellar-mass-selected volume-limited galaxy samples from the Galaxy And Mass Assembly (GAMA) survey. We also compare our measurements from GAMA with those from CosmoDC2, the simulated sky catalogue designed for Rubin Observatory LSST Dark Energy Survey Collaboration. We observe discrepancies between observations and simulations.

A Citizen science approach to finding extended radio sources in the Small Magellanic Cloud

Mr. Gideon de beer

SAAO. UCT

Abstract

The advent of high-sensitivity radio telescopes, exemplified by MeerKAT, offers an unprecedented opportunity to delve into the intricate details of extra-galactic extended radio populations. This study aims to build a catalogue comprising extended and point radio sources, drawn from MeerKAT observations of two 3°x 3° fields within the Small Magellanic Cloud (SMC). A citizen science initiative hosted on the Zooniverse platform is actively gathering data to help categorise select high signal-to-noise radio sources, distinguishing between those displaying extended emissions and those that do not. A secondary task flags the presence or absence of optical counterparts. This collaborative project's design involves comparing optical images with radio-intensity contours obtained from MeerKAT observations. Additionally, insights gained from navigating through challenges related to source-finding software applications, such as AEGEAN, and the nuanced interpretation of diverse multiwavelength data are presented. The outcomes of this research are anticipated to contribute to AI modelling by augmenting training datasets with supplementary sources. Furthermore, the findings will advance population studies in astronomy, fostering greater comprehension of radio emissions originating from the Small Magellanic Cloud and emissions beyond its boundaries.

The MeerKAT Massive Distant Clusters Survey: Probing Diffuse Radio Emission in High Redshift Clusters

Mr Dakalo Phuravhathu[1], Prof. Matt Hilton[1,2], Dr. Sinenhlanhla Sikhosana[2]

[1]University of the Witwatersrand, Johannesburg, South Africa. [2]University of KwaZulu-Natal, Durban, South Africa

Abstract

I will present an analysis of diffuse radio emission in a sub-sample of galaxy clusters at high redshifts, focusing on the most massive clusters with $z > 1$. These clusters are identified from the Atacama Cosmology Telescope (ACT) Data Release 5 catalog and are located within the DECaLS optical+infrared survey region. The MeerKAT Massive Distant Clusters Survey (MMDCS) aims to investigate the occurrence and properties of radio halos and relics in 30 merging clusters at these high redshifts, comparing them with lower-redshift samples. By using MeerKAT data, the study seeks to provide insights into the formation of diffuse radio emissions and constrain magnetic field strengths in clusters during the early universe. Preliminary results on the fraction of massive clusters hosting diffuse emission at $z > 1$ will be presented. We have currently secured MeerKAT observation time for ~14 clusters, further observations will be pursued to reach the target of 30 clusters. This study has the potential to advance our understanding of galaxy cluster evolution and magnetic field dynamics in the early universe.

A major merger as the origin of the giant stream and inner halo substructures in the Andromeda Galaxy (M31): Comparing the predictions from 1:4 merger simulations with chemodynamical data.

Mr. Charis Tsakonas[1,2,3,4,5], Dr. Souradeep Bhattacharya[2], Dr. Magda Arnaboldi[3], Prof. Francois Hammer[4], Dr. Yanbin Yang[4], Dr. Ortwin Gerhard[5], Prof. Despina Hatzidimitriou[1]

[1]National and Kapodistrian University of Athens (NKUA). [2]Inter-University Centre for Astronomy and Astrophysics (IUCAA). [3]European Southern Observatory (ESO). [4]Observatoire de Paris (ODP). [5]Max Planck Institute for Extraterrestrial Physics (MPE)

Abstract

We utilize N-body hydrodynamical simulations of a major merger (mass ratio 1:4) for M31, which reproduces its disc age-velocity dispersion relation and the morphology of its main substructures, to investigate their chemodynamical properties. Their metallicity distribution functions and phase space distributions are compared with observational data obtained for resolved stellar populations of red giant stars and planetary nebulae samples.

The model succeeds in reproducing the observed metallicity distributions at the disc edges and in the inner halo of M31. Leveraging on the model, we can account for the presence of multiple distinct ridges in the phase space of these substructures, i.e. the distinct peaks in the metallicity-line of sight velocities vs distance distributions, of the Giant Stellar stream, North East and Western shelves, as seen by DESI, SPLASH and the extended PN survey in Andromeda.

Our analysis show that over-densities in the metallicity-line of sight velocity vs radial distance - space naturally emerge as superposed loops of accreted material along the line of sight. Such distinct loops are generated by consecutive pericentric passages of the satellite, during the 1:4 merger event. The presence of accreted material at different energies and distances along the same LOS represents a viable explanation for the several observed spectroscopic properties of these substructures.

Abstract

The evolution and star formation history (SFH) of NGC 6822, an isolated dwarf irregular galaxy in the local group, has been studied utilizing evolved asymptotic giant branch (AGB) stars with a period of longer than 100 days, known as long-period variables (LPV). As LPVs pulsate, their maximum luminosity can be related to their birth mass. Padova isochrones are used to obtain the stars' birth mass, age, and pulsation duration (the period that the stars are in the LPV stage) to estimate the star formation rate (SFR) in NGC 6822. The photometric data of 329 variable stars, including LPV and spectroscopy-confirmed C-rich AGB stars, were collected from several published surveys. The SFH has been studied in two regions, the bar region and the outer region. In addition to obtaining the galaxy's SFH assuming a constant metallicity, an age-metallicity relation (AMR) is also adopted to account for the variation in the galaxy's chemical content throughout its lifetime. It is found that the onset of star formation in NGC 6822 traces back to $\sim$ 12.5 and $\sim$ 13 Gyr ago in the bar and outer regions, respectively. Furthermore, there are 3 main epochs of star formation peaking at log(t) $\sim$ 9.66 (4.6 Gyr), log(t) $\sim$ 9.21 (1.6 Gyr), and log(t) $\sim$ 7.68 (50 Myr), where t is the look-back time. The significant peak around log(t) $\sim$ 9.66 is consistent with the previous research suggesting that NGC 6822 passed through the virial radius of the Milky Way around 3-4 Gyr ago.

Studying an Early Dark Energy Model in light of the most updated cosmological datasets

Dr. Luz Ángela García

Universidad ECCI

Abstract

There is strong observational evidence of the Universe's accelerated expansion at late times. In the framework of the standard cosmological model, this effect is described through the cosmological constant Λ in the field equations. One can explain the expansion by including a dark energy component or exploring the possibility that space-time is evolving through modified gravity models. Whatever is causing the observed speeding-up of the expansion remains undetected by our telescopes.
We lean towards a Universe with dark energy, a variable matter-energy component, that causes a negative pressure in the Friedmann equations.
In this talk, we discuss a particular early dark energy model, its effective parameterization for the equation of state, and the physical motivations for its redshift dependence. Also, we describe in detail the methods we use to constrain the free parameters of such a model with the most updated observational data, as well as the Einstein-Boltzmann solver CosmoSIS and modern regression techniques. By construction, our model asymptotically tends to the fiducial value of the state equation in the De Sitter domination epoch, emulating the effect of the cosmological constant, but has a non-negligible contribution during the radiation-domination era. We provide a summary of the current cosmological proxies for this model of dark energy, the cosmic dynamics and constraints of the free parameters, and a thorough comparison with the standard model. We conclude by discussing the implications of this kind of dark energy model in the context of the Hubble tension and the growth of structure in the Universe.

Detect Cosmological Neutral Hydrogen 21cm Signal with the Tianlai Interferometer Array

Mr. Shifan Zuo

National Astronomical Observatories, Chinese Academy of Sciences

Abstract

To explore the mystery of cosmic dark energy, we need to observe the cosmic neutral hydrogen 21 cm signal, which traces the large-scale structure of the universe. The Tianlai Interferometer Array is a pioneering experiment that aims to detect this signal with a wide field of view and multiple beams. It has three parabolic cylindrical antennas and sixteen dish antennas, covering a frequency range of 700-800 MHz (corresponding to a redshift of 0.75-1.0). It uses the drift-scanning technique to collect data. Since 2016, the Tianlai Array has accumulated a large amount of data. In this presentation, we will show how we use the Tianlai Array to detect the cosmic neutral hydrogen 21 cm signal, and present the radio sky maps, the 21 cm signal power spectrum, and the multi-frequency angular power spectrum that we obtained from the data.

Deep NIR study of Galaxy Clusters in the Vela Supercluster

Dr Narges Hatamkhani

South African Astronomical Observatory

Abstract

We present the results of a deep Near-InfraRed (JHKs) analysis of six cluster candidates within the Vela Supercluster (VSCL) as part of our efforts to learn more about this large supercluster which extends across the zone of avoidance (at z~ 0.06). The observations were conducted with the InfraRed Survey Facility, situated at the South African Astronomical Observatory (SAAO) in Sutherland. The images in each cluster cover ~ 80% of their respective Abell radii. We study the structures and richnesses of the six clusters out to the cluster-centric completeness radius of r_c<1.5 Mpc and magnitude completeness limit of Ks<15.5 mag. The analysis shows VC04 to be the richest of the six. VC02 and VC05 are found to be relatively rich clusters while VC08 is rather poor. VC11 is an intermediate cluster that contains two major subclusters while VC10 has a filament-like structure and is likely not to be a cluster after all. We will also present the Ks-band Luminosity Function (LF) of VC04. We acquired spectra of galaxies in VC04 using the Southern African Large Telescope at SAAO. With this spectroscopic sample we derived the Schechter parameters of the VC04 LF to be M*=-24.41±0.44 mag, α=-1.10±0.20 and Φ*=8.84±0.20. We independently determined the VC04 LF based on the galaxy sample defined by the red-sequence method, and demonstrated that the red-sequence method is reliable and can be used in the absence of high coverage of spectroscopic information of galaxies.

Identifying strongly lensed supernova type Ia in Rubin LSST

Dr. Anupreeta More[1,2], Ms. Prajakta Mane[3], Dr. Surhud More[1,2]

[1]IUCAA. [2]Kavli IPMU. [3]IISER Mohali

Abstract

Gravitationally lensed Type Ia Supernovae (SNIa) are uniquely suited to address the Hubble constant problem in cosmology. In addition to obtaining accurate time delays, the standard candle nature of SNIa also provides additional constraints on the model of the lensing object. Finding such supernovae in the ground based imaging data from the upcoming Vera Rubin Observatory is a challenge. The multiply lensed images of the SNIa can be identified as newly appearing sources in the Difference imaging. However, these lensed supernova images are expected to be unresolved for a majority of the lenses. We use the LSST difference imaging (DI) pipeline and devise the strategy to identify such lensed supernovae. Our preliminary results suggest that we recover about 70% of injected unresolved lensed SNe in the real data from the Hyper-Suprime Cam Survey, a precursor to Rubin LSST. We also investigate and assess the suitability of color-magnitude diagram (Quimby et al. 2014) as a rapid diagnostic tool for screening genuine (un-)resolved lensed SNe Ia to be discovered from the LSST. We find that the color-magnitude space can help identify promising lensed SNe Ia whether we catch the SNe during the rising or the falling part of the light curve. The contamination from both the real and simulated core-collapse SNe is found to be not too high. We also look at variations in the color-magnitude criteria for different source redshifts and present comparison with the real populations of SNe type Ia.

Spatial Orientations of Angular Momentum Vectors of Galaxies in Supercluster S [227+006+0078] and Substructures

Dr. Janak Ratna Malla

Amrit Campus, Tribhuvan University

Abstract

We present an analysis of spatial orientations of 1217 galaxies in the supercluster S [227+006+0078]. The main goal of this work is to search for a new substructure candidate, examine the orientation of angular momentum in the framework of three different scenarios (hierarchy, pancake, and primordial vorticity models) using the “position angle-inclination method", and test the dependence on the magnitude with the spin-vector orientations and their projections. We identified two substructures using a number density contour map with a considerably high concentration of galaxies. Using the random simulation method to remove the selection effect on the database, we carried out the expected isotropic distribution using the cosmological principle. We then used three statistical tests: Chi-square, Auto-correlation, and Fourier to identify isotropy between observed and expected isotropic distributions. By analyzing the result obtained through statistical tests, we are able to confirm that the evolution of galaxies in the supercluster and substructures supports the “Hierarchy model" giving the angular momentum of galaxies in the large-scale structure tends to be oriented randomly with respect to the reference coordinate system.

Key words: Galaxies: evolution, Supercluster, Substructure, Orientation.

Study of the infall region of galaxy clusters using data from the S-PLUS project

Liana Li, Dr Claudia Oliveira

Institute of Astronomy, Geophysics, and Atmospheric Sciences of the University of São Paulo

Abstract

The influence and transformations undergone by individual galaxies and galaxy groups upon falling into rich galaxy clusters have been extensively studied, primarily focusing on the innermost regions of these structures where complete spectroscopic information is readily available in the literature. However, the more distant regions from the cluster centers, known as the infall region, where much of the action occurs, have received relatively little attention thus far. Nevertheless, a growing body of evidence in the literature has highlighted the necessity of investigating the typical environments of cluster peripheries to fully comprehend the evolution of galaxies within clusters.

This project aims to comprehensively study a sample of clusters, including regions up to 5 × R200. Comprehensive information will be obtained about the clusters themselves and their member galaxies, as well as the presence of substructure for the clusters as a whole, derived from data from the S-PLUS survey and the literature for the member galaxies.

In this context, the project aims to investigate the characteristics of galaxies in clusters, especially in the infall regions, using a sample of at least 30 clusters. The properties of galaxies will be correlated with their positions relative to substructures and filaments around the systems to determine differences attributed to pre- and post-processing processes, and to conduct a comparative study of various regions within the cluster up to the interface between the cluster and the field. To achieve this, spectroscopic and photometric data from the literature and the S-PLUS survey will be utilized.

Cosmological constraints from the EFT power spectrum and tree-level bispectrum of 21cm intensity maps

Mr Liantsoa Finaritra Randrianjanahary

University of the Western Cape, South Africa

Abstract

We explore the information content of 21cm intensity maps in redshift space using the 1-loop Effective Field Theory power spectrum model and the bispectrum at tree level. The 21cm signal contains signatures of dark matter, dark energy, and the growth of large-scale structure in the Universe. These signatures are typically analyzed via the 2-point correlation function or power spectrum. However, adding the information from the 3-point correlation function or bispectrum will be crucial to exploiting next-generation intensity mapping experiments. The bispectrum could offer a unique opportunity to break key parameter degeneracies that hinder the measurement of cosmological parameters and improve on the precision. We use a Fisher forecast analysis to estimate the constraining power of the HIRAX survey on cosmological parameters, dark energy and modified gravity.

Spectro-polarimetric view of the gamma-ray emitting NLS11H0323+342

Mr. Jincen Jose[1,2], Dr. Suvendu Rakshit[1], Dr. Swayamtrupta Panda[3]

[1]Aryabhatta Research Institute of Observational Sciences (ARIES), India. [2]Center for Basic sciences, Pt. Ravishankar Shukla University, Raipur, Chhattisgarh, India. [3]Laborat ório Nacional de Astrof ísica - MCTI, R. dos Estados Unidos, Brazil

Abstract

The gamma-ray emitting narrow-line Seyfert 1 galaxies are a unique class of objects that launch powerful jets from relatively lower-mass black hole systems compared to the Blazars. However, the black hole masses estimated from the total flux spectrum suffered from the projection effect, making the mass measurement highly uncertain. The polarized spectrum provides a unique view of the central engine through scattered light. We performed spectro-polarimetric observations of the gamma-ray emitting narrow-line Seyfert 1 galaxy 1H0323+342 using SPOL/MMT. The degree of polarization and polarization angle is 0.122 ± 0.040% and 142 ± 9 degrees, while the Hα line is polarized at 0.265 ± 0.280%. We decomposed the flux spectra and estimated broad Hα FWHM of 1015 km/s. The polarized flux spectrum shows a broadening similar to the total flux spectrum with a broadening ratio 1.22. The Monte Carlo radiative transfer code 'STOKES' applied to the data provides the best fit for a small viewing angle of 9-24 degrees and a small optical depth ratio between the polar and the equatorial scatters. A thick BLR with significant scale height can explain a similar broadening of polarized spectra compared to the flux spectra together with a small viewing angle.

Combining large radio and optical astronomical surveys: finding galaxy cluster members using the MeerKAT Galaxy Cluster Legacy Survey.

Mr Johan Nel, Prof. Ilani Loubser

Centre for Space Research, North-West University

Abstract

In the coming years, we will see a rise in the number of large radio surveys targeting the unexplored Southern sky from SKA-precursor telescopes, e.g. MeerKAT. To help increase the scientific impact of these surveys, we set out to combine radio surveys with optical surveys by using the Likelihood Ratio method. In this work, we illustrate the power of cross-matching sources in these wavelengths by combining the MeerKAT Galaxy Cluster Legacy Survey with DECaLS data. We show an application by using photometric redshifts in the form of probability distribution functions to calculate the probability that an individual galaxy is a cluster member. This information can, in turn, be used to derive galaxy cluster properties.

Evolution of Galaxies and their central Black Holes in Cosmological Hydrodynamical Simulations

Dr. Paramita Barai

INAF - Osservatorio Astronomico di Trieste (Italy)

Abstract

Galaxy formation is highly non-linear, and involves a complex interplay of distinctive processes over a wide range of physical scales. Feedback from star-formation (molecular clouds on the pc scale), stellar evolution, and supernova (SN) explosions as mass/energy ejection play crucial roles in the build up of galaxies and large-scale structures. Simultaneously, accretion of matter onto central Supermassive Black Hole (SMBH)s in massive galaxies liberates enormous amounts of feedback energy, which affects the environment from pc to Mpc scales, often generating powerful AGN outflows observed at multi-wavelengths. Numerical methods are ideal to tackle these sophisticated physics of galaxies and intervening gas. Cosmological Hydrodynamical Simulation, executed on massively parallel petaflop computing platforms, has emerged as a powerful tool to produce cosmic structures that are similar to the observed ones.

I will describe the performance and analyses of Cosmological Hydrodynamical Simulations, emphasizing on the growth and feedback from SMBHs at galaxy centers. These simulations are done with a modified version of the SPH code GADGET-3, and includes sub-resolution prescriptions for the physical processes of cooling, star-formation, chemical evolution, SN and AGN feedback. Especially we have sub-resolution models of thermal and kinetic AGN feedback, and switching between the feedback modes depending on the BH accretion rate. We investigate the growth of supermassive BHs, as well as their impact on the host galaxies in terms of star formation quenching and the formation of outflows.

Galaxy cluster mass estimation through photometry

Lucas Gabriel Silva, Professor Laerte Sodré Jr

Instituto de Astronomia, Geofísica e Ciências Atmosféricas da Universidade de São Paulo (IAG/USP)

Abstract

The mass of galaxy clusters plays a crucial role in understanding galaxy evolution and large-scale structure, providing essential constraints for cosmological models. In this work, we explore a photometric approach for mass estimation, focusing on identifying the distinctive sharp transition in the cluster profile slope, commonly known as the splashback radius (Rsb). Our findings suggest that this radius can be reliably estimated by modeling cumulative galaxy counts from the cluster center, employing models derived from recent advancements in numerical simulations. We analyze samples from the Sloan Digital Sky Survey (SDSS) within the redshift range of $0 < z < 0.6$, utilizing photometric redshifts to assign cluster membership. Our results indicate robust Rsb estimations, regardless of the adopted magnitude limit, exhibiting a significant correlation with M200 masses obtained from weak-lensing analyses, with a dispersion of ≈ 0.2 dex. These findings pave the way for advancements in galaxy cluster astrophysics, offering the exciting prospect of accurately estimating cluster masses using solely photometric data.

[4]Center for Astrophysics | Harvard & Smithsonian. [5]Cahill Center for Astronomy and Astrophysics, California Institute of Technology. [6]Masaryk University

Abstract

Dwarf highly star-forming galaxies dominated the early Universe and are considered the main driver of its reionization. Direct observations of these very distant galaxies are limited mainly to rest-frame ultraviolet and visible wavelengths, and as a result, some of their properties are out of reach. Therefore, the study of their local analogs, the Green Pea (GP) and Blueberry (BB) galaxies is still paramount. This work expands the number of known BBs to smaller distances (< 200 Mpc) and the south equatorial sky and examines their properties probed by visible and infrared (IR) light. The selected BBs are compared with GPs and other dwarf star-forming galaxies (SFGs). This work has identified 48 BBs out of which 40 are newly discovered. The nearest BB lies at 19 Mpc while 14 BBs are in the south equatorial sky. The BBs tend to be extremely IR red in both WISE W1-W2 and W2-W3 colors, located in different positions in this diagram compared to typical SFGs. Overall, dwarf SFGs with higher specific star-formation rates tend to have redder IR colors. Although GPs and BBs share many similarities, the latter are the most intensively star-forming sources of the local Universe among dwarf galaxies. Overall BBs are intrinsically bluer in visible light, redder in the IR, less massive, have higher specific star-formation rates and equivalent widths, lower metallicities, and have the most strongly ionized interstellar medium compared to typical SFGs and GPs.

Estimating Ages for Star Clusters in PHANGS Galaxies Using a Combination of HST and JWST

Bradley Whitmore

Space Telescope Science Institute - Emeritus

Abstract

The ability to accurately measure the ages of star clusters is a critical component in our quest to understand the interplay and evolution of giant molecular clouds, star clusters, feedback, and the destruction of star clusters. While the addition of JWST data promises to improve our age estimates in the long run, a number of challenges need to be overcome before this becomes a reality. This includes the effects of degeneracies between age/reddening/metallicity, the effects of outflows from feedback that remove the gas and dust within just a few million years, and triggering of new star clusters on the edges of super-bubbles. Currently, most SED modeling codes that incorporate IR emission (e.g., Draine models) are designed for integrated populations, and assume energy balance to compute re-emission in the IR from the dust reddening of starlight. However, the problem is much different for the modeling of young star clusters because the dust emission and heating sources do not appear in the same aperture due to outflows that remove the gas and dust from their central regions in only a few million years. As part of our effort to understand this phenomena, and to improve our age-dating, we present a set of empirical HST+JWST SED templates for star clusters for a range of ages. A key result is the finding that essentially all star clusters with strong PAH and IR continuum emission have ages of 5 My or younger.

NGC 6240: triple SMBH evolution with von Zeipel-Lidov-Kozai oscillation

Dr Maryna Ishchenko, Dr Peter Berczik, Ms Margaryta Sobolenko

Main Astronomical Observatory, National Academy of Sciences of Ukraine

Abstract

One of the possible ways of creating the supermassive black hole (SMBH) is hierarchical merging scenario. Central SMBHs at interacting and coalescing host-galaxies are observed as SMBH binary candidates at different separations from hundreds of pc to mpc.

To build the initial physical model, the estimated parameters of the stellar and gas components and central black holes were collected based on existing observational data. The observed separation between S1 and S2 is ΔR = 198 pc. The observed separation between N and the dynamical center of binary S1 + S2 is ΔR = 856 pc, according to Kollatschny et al. (2020).

The main goal of our N-body dynamical modeling was to reach the evolution of merge S1 + S2 system together with and the northern component N1. For the global dynamical integration, we used the high-order parallel N-body code ϕ−GPU which is based on the fourth-order Hermite integration scheme with hierarchical individual block time steps.

According to our simulation results, for all models and random-randomizations, the bound system from S1+S2 components is formed at ∼3.6 Myr. The formation of a triple bound system S+N occurs at ∼18 Myr. During the simulation of the evolution of triple SMBH and their surrounding environment in NGC 6240, the von Zeipel-Lidov-Kozai oscillation was detected for the binary components S (the center of mass of the S1+S2 systems) and N. The inclination angle between the orbital angular momentum of binary components is well coincide with theoretical calculations.

Supermassive black hole binary in NGC5419: Studying the evolutionary phases of early-type galaxies

Dr. Bianca Neureiter[1,2], Dr. Jens Thomas[1,2], Dr. Kianusch Mehrgan[1,2], PD Dr. Roberto Saglia[1,2], Dr. Stefano de Nicola[1,2], Prof. Dr. Ralf Bender[1,2], Dr. Antti Rantala[3], Dr. Thorsten Naab[3]

[1]Max Planck Institute for extraterrestrial Physics. [2]University Observatory Munich. [3]Max Planck Institute for Astrophysics

Abstract

The most massive elliptical galaxies are known to display a central deficit of stars. Depleted 'cores' are believed to form in dry mergers between early-type galaxies (ETGs) via a process called core scouring. This phenomenon leaves a unique imprint in the stellar signature, making it an ideal tracer for investigating the formation history of ETGs.
Through the analysis of the massive elliptical core galaxy NGC5419, we identified a particularly suitable object to prove this proposed dry merging scenario in greater detail.
NGC5419 features a well-depleted core. However, the presence of a double nucleus in HST data suggests that two supermassive black holes (SMBHs) from the progenitor galaxies have not yet completely merged. By applying a novel state-of-the-art dynamical modeling technique (MNRAS_500_1437, MNRAS_519_2004) to high-resolution MUSE spectral data of this galaxy, we analysed its orbit distribution in greater detail.
We find that NGC5419 is indeed observed in an intermediate core evolution phase, hosting an as-yet-unmerged BH binary system. NGC5419 is the first galaxy observed in this state and therefore confirms previously unobserved insights into the formation mechanism of ETGs.
Our dynamical models of NGC5419 moreover reveal a total BH binary mass of Mbh = (1.0 ± 0.08) × 10^10 Msol, establishing NGC5419 as host to one of the most massive BHs discovered in the local universe so far (ApJ_950_15). Given the limited number of previously identified black holes in the 10 billion solar mass range, NGC5419's black hole determination contributes to the quest for 'dead quasars' in our local universe.

The power of UV and optical-IFU observations for understanding the low luminous universe

Dr MOUSUMI DAS

Indian Institute of Astrophysics

Abstract

It is well known that far-UV and near-UV observations can trace star formation in galaxies for longer periods and over a broader range of stars (O, B, A) compared to Halpha which traces emission from massive O type stars only. This is especially important for observing star formation in diffuse and metal poor stellar disks. For example, studies have shown that UV can detect star formation from low stellar density environments such as the extended UV (XUV) disks of nearby galaxies and the tidal arms in interacting galaxies. On the other hand integrated field spectroscopy (IFU) can detect ionized gas emission and their velocity fields in star forming and AGN host galaxies. In this study we show that the combination of the two, UV and optical-IFU observations, is a powerful tool in mutiwavelength Astronomy. The UV imaging combined with the spectroscopic information from the IFU observations, is important for understanding the stellar and gas distribution. Using this combination one can detect new galaxies, trace star formation in diffuse stellar environments, identify counter-rotating disks as well as detect AGN activity and outflows. Our studies use the ASTROSAT Ultraviolet Imaging Telescope (UVIT) combined with MUSE and SDSS-MANGA observations, as well as near-infrared images to study the stellar disks. Using several UVIT and IFU studies that we have done as examples, we demonstrate that UV and optical multiwavelength studies are essential for understanding star formation and AGN activity in low luminosity galaxies.

Whispers from the Unknown: Probing the Dark Matter mystery with MeerKAT.

Ms Natasha Lavis[1], Dr Michael Sarkis[2], Dr Geoff Beck[1], Dr Kenda Knowles[3]

[1]Centre for Astrophysics, University of the Witwatersrand. [2]Department of Physics, University of Stellenbosch. [3]Centre for Radio Astronomy Techniques and Technologies Department of Physics and Electronics, Rhodes University

Abstract

As we attempt to unveil the hidden nature of dark matter (DM), MeerKAT, the precursor to the Square Kilometre Array (SKA) based in South Africa, takes center stage. With superior capabilities in the L and U bands, MeerKAT's advanced angular resolution and sensitivity make it ideal for WIMP dark matter investigations.

Drawing on MeerKAT Galaxy Cluster Legacy survey data, we assess MeerKAT's constraining prowess. Through meticulous observations and simulations of diffuse synchrotron DM signals, we achieve competitive constraints on WIMP annihilation across three orders if magnitude in mass, surpassing results from gamma-ray experiments like Fermi-LAT and HESS. Our emphasis lies in refining our analysis techniques. In particular, we aim to investigate the effect of an improved dynamic range of the data which we expect would allow us to probe even fainter signals.

In this presentation, we spotlight MeerKAT's and South Africa's contributions, showcasing advancements in radio interferometry that lead to tighter constraints and elevate our understanding of the elusive dark matter.

A novel Bayesian approach for decomposing the radio emission of quasars

Bohan Yue, Philip Best, Kenneth Duncan

University of Edinburgh

Abstract

Studies show that both radio jets from the active galactic nuclei (AGN) and the star formation (SF) activity in quasar host galaxies contribute to the quasar radio emission, yet their relative contributions across the population remain unclear. Here, I will present new constraints on the SF and AGN contribution to the quasar radio emission and their evolution with various physical processes, using an improved Bayesian parametric model that allows us to statistically separate the SF and AGN components in observed quasar radio flux density distributions. I will present new results based on the LOFAR Two-Metre Sky Survey Data Release 2, showing a quasar host galaxy SFR evolution that increases with bolometric luminosity and with redshift out to redshift ~4. The prevalence of radio AGN emissions increases with quasar luminosity, but has little dependence on redshift, indicating the AGN jet strength is mostly governed by local activities. Our new methodology and large sample size also allow us to investigate the role of parameters including quasar colour and black hole mass on quasar radio emission. I will show that the radio excess in red quasars is due to an enhancement in AGN-related emission and that this radio enhancement occurs mostly in quasars with weak or intermediate radio power. Furthermore, I will present our newest results on the black hole mass dependency of quasar radio emissions. This methodology holds great potential in revealing the mechanism behind quasar radio emissions under the extra parameter space to be explored by SKA and its pathfinder missions.

Chemical modeling of methanol as an extragalactic shock tracer

Eva Méndez[1], Dr. Ko-Yun Huang[2], Prof. Serena Viti[2,3], Prof. Mario-A. Higuera-G.[1]

[1]Observatorio Astrónomico Nacional, Universidad Nacional de Colombia, Teusaquillo, Bogotá, Bogota, Colombia. [2]Leiden Observatory, Leiden University, PO Box 9513, NL - 2300 RA Leiden, The Netherlands. [3]Department of Physics and Astronomy, University College London, Gower Street, London WC1E6BT, UK

Abstract

The behavior of methanol in the composite galaxy NGC 1068 was analyzed to investigate its effectiveness as an extragalactic shock tracer and to study the effect of shock velocity and formation routes on the predicted interstellar abundance of CH_3OH. With a parameterized C-shock physical model, C-shock chemistry was investigated with UCLCHEM to study the chemical abundance of CH_3OH as a function of time in different locations of the CND and the SB ring of NGC 1068. It is concluded that gaseous methanol can trace C-type shocks as its abundance increases significantly due to ice sputtering or sublimation during shock propagation. This increase is comparable from both low- (∼10 km/s) and high- (∼50 km/s) velocity shocks. Comparing our models with the multi-line molecular observations and analysis performed by Huang et al. submitted, we concluded that the observed CH_3OH abundance may result from C-shock influence or from thermal sublimation of ice due to protostellar core heating. This work also demonstrated for the first time that the primary reaction leading to the formation of methanol in interstellar ices is the radical-molecule H-atom abstraction route under shocked-influenced environments, such as the CND of NGC 1068, from the modeling point of view. This finding is consistent with the results from Santos et al. 2022 and Simons et al. 2020 in dark molecular clouds. However, its dominance is dependent on the gas kinetic temperature (T_k), gas volume density (nH_2), velocity of the C-shock wave (v_{shock}), and cosmic ray ionization rate (ζ).

Kinematics of strongly and weakly barred galaxies

Dr Tobias Géron

University of Toronto

Abstract

We used the Tremaine-Weinberg method with MaNGA IFU data to study the bar kinematics of a sample of 225 strong and weak barred galaxies, the largest sample to date. We found that the bar pattern speed is significantly lower for strongly barred galaxies, compared to weakly barred galaxies. Simulations show that the pattern speed decreases as the bar evolves and exchanges angular momentum with its host. Therefore, our results suggest that strongly barred galaxies are more evolved and older structures than weakly barred galaxies. The corotation radius is not significantly different between weakly and strongly barred galaxies. Interestingly, R, the ratio between the corotation radius and the bar radius, is significantly lower for strongly barred galaxies than for weakly barred galaxies. This ratio delineates "ultrafast" ($R < 1.0$), "fast" ($1.0 < R < 1.4$) and "slow" ($R > 1.4$) bars. Simulations predict that fast bars are typically triggered by global bar instabilities, while slow bars are triggered by tidal interactions. Thus, our results show strong bars are more likely to be triggered by global bar instabilities than weak bars. However, interestingly, we find no correlation between bar pattern speeds and measurements of the environment. Additionally, our fraction of ultrafast bars is lower than most other studies, which decreases the recently claimed tension with ΛCDM. We also explore the effects of the bar kinematics on the dark matter fraction, obtained through JAM modelling, as well as other galaxy properties, such as gas content and the presence of a bulge.

The effects of bar strength and kinematics on galaxy evolution: slow strong bars affect their hosts the most

Dr Tobias Géron

University of Toronto

Abstract

We study how bar strength and bar kinematics affect star formation in different regions of the bar. This is done by creating radial profiles of resolved EW[Hα] and Dn4000 measurements obtained from MaNGA. We classified bars as strong or weak using the automated classifications of Galaxy Zoo DESI, and classify bars as fast or slow using the Tremaine-Weinberg method. We find that, in agreement with previous studies, strong bars in star forming galaxies have increased star formation in their centre and beyond the bar-end region, while star formation is suppressed in the arms of the bar. This is not found for weakly barred galaxies. We also find that slow bars in star forming galaxies have significantly higher star formation along the bar than fast bars, especially if the bar is also strong. Interestingly, the global star formation rate is not significantly different between fast and slow bars. This suggests that the kinematics of the bar does not affect star formation globally, but changes where star formation occurs in the galaxy. We hypothesize that this is due to the fact that the slower bars encounter more gas in their galaxies as the stellar and gas discs rotate past them, leading to funnelling of gas from the outskirts of the galaxy along the bar. In summary, we find that a bar will influence the total amount of star formation and its distribution the most if it is both strong and slow.

Stellar population properties and morphology of massive compact galaxies at z ~ 0

Ms. Katia Slodkowski Clerici[1], Dr. Allan Schnorr-Müller[1], Dr. Marina Trevisan[1], Dr. Tiago Vecchi Ricci[2]

[1]Universidade Federal do Rio Grande do Sul. [2]Universidade Federal da Fronteira Sul

Abstract

Quiescent galaxies have low star formation activity, old, metal-rich stellar populations, large bulge-to-total mass ratios, and high mass surface densities within 1 kpc. However, quiescent galaxies observed at higher redshifts differ significantly from their local counterparts; for example, they are extremely more compact. Due to their small sizes and faint stellar continua, spectroscopic studies of large samples are extremely challenging with current facilities. As an alternative, massive compact galaxies (MCGs) at low redshifts can be explored as local analogues. To better understand the MCGs and enhance the discussion about their formation and evolution, we studied the stellar population properties of a large sample of 1858 MCGs from the Sloan Digital Sky Survey. We compared their stellar population properties with a control sample of average-sized quiescent (CSGs) at fixed velocity dispersion. We found that MCGs are older, have higher [α/Fe] and lower metallicities, except for velocity dispersion higher than 230 km/s where MCGs and CSGs have similar ages and [α/Fe]. We suggest that progenitor bias effects can explain the differences in age and in [α/Fe], while the origin of the differences in metallicity is still unclear. Additionally, we fitted the 2D surface-brightness of 250 MCGs from the Hyper Suprime-Cam at the Subaru telescope. Our analysis showed that around 7%, 50%, and 43% of MCGs can be well-described using one, two, and three components, respectively. These components include a Sérsic bulge with n ~ 4, a disk with n = 1, and an external Sérsic component with n ~ 1.7.

The Gravitational Lensing Imprints of DES Y3 Superstructures on the CMB: A Matched Filtering Approach

Mr Umut Demirbozan

Institut de Física d'Altes Energies(IFAE). Universitat Autònoma de Barcelona (UAB)

Abstract

Low density cosmic voids gravitationally lens the cosmic microwave background (CMB), leaving a negative imprint on the CMB convergence κ. This effect provides insight into the distribution of matter within voids, and can also be used to study the growth of structure. We measure this lensing imprint by cross-correlating the Planck CMB lensing convergence map with voids identified in the Dark Energy Survey Year 3 data set, covering approximately 4,200 deg2 of the sky.

We use two distinct void-finding algorithms: a 2D void-finder which operates on the projected galaxy density field in thin redshift shells, and a new code, Voxel,which operates on the full 3D map of galaxy positions. We employ an optimal matched filtering method for cross-correlation, using the MICE N-body simulation as a representative of ΛCDM model both to establish the template for the matched filter and to calibrate detection significances.

Using the DES Y3 photometric luminous red galaxy sample, we measure $A\kappa$, the amplitude of the observed lensing signal relative to the simulation template, obtaining $A\kappa$ = 1.03 ± 0.22 (4.6σ significance) for Voxel and $A\kappa$ = 1.02 ± 0.17 (5.9σ significance) for 2D voids, both consistent with ΛCDM expectations. Our study is uique in the sense that we compare two different stacking/filtering methods and show how they compare.

We find that the leading source of noise in our measurements is Planck convergence noise, implying that future data from the Atacama Cosmology Telescope (ACT), South Pole Telescope (SPT) and CMB-S4 will increase sensitivity and allow for more precise measurements.

X-ray Properties and Scaling Relations of Galaxy Clusters at redshift > 0.2 in the X-CLASS Survey

Dr Mona Molham

The National Research Institute of Astronomy and Geophysics (NRIAG)

Abstract

There are power-law relations between X-ray observables of galaxy groups and clusters at different redshift and mass scales. These relations are used to link the physical properties of clusters at cosmic scales, probe the evolution of the large-scale structure, and constrain cosmological parameters through cluster counts.

The XMM Cluster Archive Super Survey, X-CLASS, is a serendipitous search of X-ray-detected galaxy clusters in 4176 XMM-Newton archival observations until August 2015 (Koulouridis et al. 2021, A&A 652, A12). The catalog consists of 1646 well-selected X-ray-detected clusters over a wide sky area, along with their selection function. It spans a wide redshift range up to z ~ 1.5, with 982 clusters spectroscopically confirmed. We will investigate the scaling relations between X-ray observables of the clusters and study the spectral and radial properties of the intracluster medium (ICM). The results from this study will be the base for the cosmological studies in the X-CLASS survey and comparison studies with other surveys compiled from other X-ray missions (e.g. eROSITA, Chandra).

Are Odd Radio Circles phoenixes of powerful radio galaxies?

A/Prof Stas Shabala

University of Tasmania

Abstract

Odd Radio Circles (ORCs) are a class of low surface brightness, circular objects approximately one arcminute in diameter. ORCs were recently discovered in the Australian Square Kilometre Array Pathfinder (ASKAP) data, and subsequently confirmed with follow-up observations on other instruments -- yet their origins remain uncertain. In this talk, I will show that ORCs can be formed from the interaction of two common processes in galaxy groups and clusters: remnant lobes of powerful radio galaxies being re-energised by the passage of a shock. Using relativistic hydrodynamic simulations with synchrotron emission calculated in post-processing, I show that buoyant evolution of remnant radio lobes is alone too slow to produce the observed ORC morphology. However, the passage of a shock can produce both filled and edge-brightened ORC-like morphologies for a wide variety of shock and observing orientations. Circular ORCs are predicted to have host galaxies near the geometric centre of the radio emission, consistent with observations of these objects. Significantly offset hosts are possible for elliptical ORCs, potentially causing challenges for accurate host galaxy identification. Observed ORC number counts are consistent with a paradigm in which moderately powerful radio galaxies are their progenitors.

Exascale Science in the Desert: Building on the Big Data Precursors

Dr Jordan Collier

Curtin Institute of Radio Astronomy (CIRA). Inter-University Institute for Data Intensive Astronomy (IDIA). Western Sydney University

Abstract

The Square Kilometre Array (SKA) is a global multi-billion dollar project set up to build and operate the world's largest telescope, primarily located within the desert regions of the Murchison, Western Australia, and the Northern Karoo, South Africa. To fully exploit the scientific output of the immense amount of data flowing from the telescopes, the SKA Observatory (SKAO) is working with science communities across the world through SKA Regional Centres (SRCs), which are nationally lead hubs containing infrastructure for supporting the science and computing required by this international community.

In this presentation, I will cover the broad and diverse scientific projects facilitated by the SRCs and their prototypes in Australia and South Africa, namely the Australian SRC (AusSRC), and the Inter-University Institute for Data-Intensive Astronomy (IDIA), including my own research interests investigating Odd Radio Circles (ORCs) and young and distant radio galaxies, and our use of the ilifu facility, operated by IDIA, and the Pawsey Supercomputing Centre, to analyse these data. In particular, I will focus on our current support for the SKA Precursors, the MeerKAT Radio Telescope, the Murchison Widefield Array (MWA), and Australian SKA Pathfinder (ASKAP), in themselves routinely producing big data, as well as our future plans to build on top of this to develop the capabilities essential to facilitating SKA science, in preparing for SKA data at the exabyte scale.

HI Intensity Mapping Survey with FAST Drift Scan Observation.

Dr. Yichao Li

Northeastern University

Abstract

The HI intensity mapping is a promising way to probe the large-scale structure (LSS) of the Universe. It has been explored using different survey experiments, such as the Green Bank Telescope, Parkes Telescope, MeerKAT, and Five-hundred-meter Aperture Spherical Telescope (FAST). A couple of specially designed HI intensity mapping facilities, such as Tianlai, CHIME, BINGO, and HIRAX, are under construction or collecting data. The HI intensity mapping technique is also proposed as the major cosmology project with the Square Kilometre Array in the near future. However, cosmic HI LSS detection with intensity mapping is still underway. The major challenge comes from the foreground residual, which is primarily induced by instrumental effects or inaccurate calibration. Such systematic effect needs to be either well-controlled or eliminated. In this talk, I will present our recent efforts in building an accurate data analysis pipeline for the HI intensity mapping survey with FAST, and the foreground subtraction method based on deep learning to eliminate the systematic effect.

Investigating star formation rates as a function of the galaxy clusters environment using the MeerKAT telescope.

Dr Kabelo Kesebonye

University of the Witwatersrand

Abstract

This study presents the study of star formation (SF) activity in 20 clusters of different dynamical states at redshifts $0.15 < z < 0.35$ using dust-unbiased radio luminosities from the MeerKAT radio telescope. We use optical data from the Dark Energy Camera Legacy Survey (DECaLS) to estimate photometric redshifts using the zCluster SED-fitting algorithm. We use radio diffuse emission in the form of haloes and relics as a proxy for cluster merger activity, and we divide our cluster sample between disturbed/merger clusters and relaxed clusters. This study presents the first statistical investigation of SF activity in clusters using MeerKAT-detected galaxies. It leverages the large field of view coverage by MeerKAT to investigate the relation between SF activity and the environment in clusters of different dynamical states out to 2R200. We observe a higher fraction of star-forming galaxies (fSF) in disturbed clusters than in relaxed clusters. Disturbed clusters also exhibit higher masses (M200) and total star formation rates (∑SFR) than relaxed clusters. On analysing the redshift evolution of mass-normalised ∑SFR, we observe a ≅4 times decline in SF activity from a redshift of 0.35 to 0.15, corresponding to ≅2 Gyr in look-back time. Our result is roughly consistent with cluster studies using infrared-derived SFR (≅5 times decline) at a similar redshift slice as our sample.

Abstract

The neutral hydrogen (HI) 21-cm Intensity Mapping signal is a promising probe for the large-scale structures in the Universe. Here, we present a tight upper limit on the HI mass density and the HI bias $[\Omega_{HI} * b_{HI}] < 0.010$ at the redshift z = 2.2. The upper limit is within an order of magnitude of the expected signal, and we have achieved this result by removing the foregrounds from a 25-hour uGMRT interferometric observation at the frequency interval 394-494 MHz. The technique we use has two steps: first, we estimate the multifrequency angular power spectrum (MAPS) using the Tapered Gridded Estimator (TGE), which suppresses the bright point sources that appear through the sidelobes of the telescope. Then, we remove the residual foregrounds from the measured MAPS by using our newly developed polynomial fitting and Gaussian process regression techniques. We find the power spectrum to be consistent with noise in the entire Fourier space. We plan to observe longer to make a detection. The techniques and the results are encouraging for ongoing and future 21-cm intensity mapping surveys with MeerKAT and SKA-mid.

The Evolution of the Galaxy Stellar Mass Function in Sunyaev-Zel'dovich Selected Galaxy Clusters from ACT DR5

Mr. Damien Cole Ragavan[1], Prof. Matt Hilton[1,2]

[1]University of the Witwatersrand. [2]University of KwaZulu-Natal

Abstract

An important observable of galaxy populations is their stellar mass function (SMF), which describes the number density of galaxies as a function of stellar mass. In the context of galaxy clusters, which are massive gravitationally-bound systems, the SMF becomes particularly important as it provides crucial information about the distribution of stellar masses within clusters and the mechanisms that lead to this observed distribution. Thus, accurate measurements of the cluster SMF can help us understand the impact of the cluster environment on galaxy formation and evolution. In this presentation, I will discuss the role of the galaxy SMF in galaxy clusters and present our current work on this topic. In this work, we will be studying the galaxy population of a large sample of Sunyaev-Zel'dovich (SZ) selected galaxy clusters, drawn from the fifth data release of the Atacama Cosmology Telescope (ACT DR5), by measuring their composite cluster SMFs using optical data from the Dark Energy Camera Legacy Survey (DECaLS). Taking advantage of accurate photometry from DECaLS, photometric redshifts will be used to construct redshift-binned and cluster mass-binned composite SMFs. This type of SMF study has never been performed on this specific cluster sample. Implementing these methods on the ACT DR6 cluster sample (yet to be released) using deep photometry from the Large Synoptic Survey Telescope (LSST) is a logical way forward for this research.

Abstract

Using the deep observations from the *Ultraviolet Imaging Telescope (UVIT)* onboard *AstroSat,* we report the direct detection of Lyman Continuum (LyC) emission from 9 galaxies and 1 Active Galactic Nuclei (AGN) at the cosmic noon ($z \sim 1.1$-1.6) in the GOODS-North field. The restframe UV wavelength of the sources are in the extreme-ultraviolet (EUV) regime $\sim$ 550-700 Å, the shortest LyC wavelength range probed so far. The absolute escape fraction of the sources span a range $\sim$ 10 - 55 %, estimated from the far-ultraviolet (FUV) and Hα line luminosities using Monte Carlo (MC) analysis of two Inter-Galactic Medium (IGM) models. Due to the instrumental limitations of previously available facilities, this redshift range had remained devoid of direct detections of LyC emission. With *UVIT* having a very low detector noise, each of these sources are detected with an individual signal-to-noise ratio (SNR) > 3 while for the stack of six sources, we achieve an SNR $\sim$ 7.4, making it the first coherent sample of the Lyman continuum leakers at this epoch. In most of the sources the LyC emission is observed to be offset from the optical centroids and extended beyond the *UVIT* PSF of 1.''6. This sample fills an important niche between *GALEX* and *Cosmic Origins Spectrograph (COS)* at low-*z*, and *HST* WFC3 at high-*z* and is crucial in understanding the evolution of LyC leakers.

Probing the baryonic cycle of z~5 star-forming galaxies from the ALMA Large-Program *ALPINE*

Mr Prasad Sawant

National Centre for Nuclear Research, Poland

Abstract

The early growth phase of the Universe (6 > z > 4) marks a pivotal transition between the primordial galactic formation and the onset of the peak of cosmic star formation rate density. During this phase, galaxies are rapidly growing in mass and size, fueled by the intricate interplay of gas and dust within the interstellar medium (ISM). Constraining the evolution of these galaxies is a challenge owing to degeneracies in cosmological simulations and chemical evolution models.

In this work, we make use of chemical evolution models to probe the baryonic evolution of z~5 main-sequence star-forming galaxies as part of the ALMA Large Program ALPINE. We utilize panchromatic observations to perform spectral energy distribution fitting for these galaxies, employing both Chabrier and top-heavy initial mass functions (IMFs) to derive the physical parameters (i.e stellar mass, star formation rate and dust mass).

Our models successfully reproduce the gas and dust content in most of these primordial galaxies, indicating dust production primarily through Type II supernovae and gas/dust removal via galactic outflows and moderate inflow of primordial gas. Furthermore, a subset of these galaxies displays rapid dust build-up in shorter timescales (~20 Myr - 100 Myr), which is partially reconcilable with a top-heavy IMF. These findings, coupled with upcoming studies driven by James Webb Space Telescope observations will help us bridge the gap between observations and models, shedding new light on dust production mechanisms in the early universe.

Multipoles of the redshift-space power spectrum from SKAO and other surveys

Mr. Ron Baatjes

University of the Western Cape

Abstract

The large-scale distribution of neutral hydrogen in the late Universe provides a probe of the underlying distribution of matter, which is a powerful complement to the standard probe delivered by galaxy number counts. Measuring the neutral hydrogen distribution with MeerKAT, SKAO and other radio telescopes through the hydrogen 21 cm line emission, has the potential to become a key cosmological probe in the coming years. We will investigate the cosmological constraining power of the 21 cm intensity mapping power spectrum in redshift space. To this end, we will decompose the power spectrum into multipoles, modelling the effects of foreground avoidance, telescope beam,instrumental noise and the bias of 21 cm intensity fluctuations. Then we will use Fisher forecasting methods to estimate the precision that is obtainable by proposed surveys on MeerKAT (the 64-dish precursor array of the SKA Observatory), on the full SKAO, and potentially on other dish arrays such as HIRAX. Measurements of the power spectrum multipoles enable measurements of key cosmological parameters and we will estimate the precision of such measurements. In particular, the multipoles provide an estimate of the growth rate of large-scale structure, which can deliver tests of the theory of gravity.

Cosmic Dynamics Unveiled: A Relativistic Approach to Structure Formation and Evolution

Mr Kennedy Konga[1], Dr Dismas Wamalwa[1], Dr Dickson Kinyua[2], Dr Daniel Memeu[1]

[1]Meru University of Science and Technology, Kenya. [2]Kirinyaga University, Kenya

Abstract

Modern cosmology is broadly based on the Cosmological principle, which assumes homogeneity and isotropy as its foundational pillars. Thus, there is not much debate about the metric (i.e., Friedmann-Lemaitre-Robertson-Walker; FLRW) one should use to describe the cosmic space-time. But Einstein's equations do not unilaterally constrain the constituents in the cosmic fluid, which directly determine the expansion factor appearing in the metric coefficients. As its name suggests, ΛCDM posits that the energy density is dominated by a blend of dark energy (typically a cosmological constant, Λ), cold dark matter (and a "contamination" of baryonic matter), and radiation. We propose a model founded on redshift, light intensity, and number density per solid angle of galaxies as the three key astronomical parameters. We explore these parameters with models of different geometries (i.e. open, closed, or flat). Our analysis implores that the model can account for both accelerated and decelerated expansion of the universe. Our analytical solutions and simulations describe patterns of formation and evolution of cosmic structures. There is great activity at redshifts after which there is gradual progress until an indication of a nursery for the formation of most cosmic structures. At redshifts we observe a gradual decline in activity until where it flattens. This transition is directly related to the matter density and is dependent on the geometry of the universe. The model explains the intricate connections between cosmic acceleration and deceleration hence elucidating the formation of structures, dynamics, and evolution of the universe.

Prospects of Measuring the 21cm Signal with HERA using $21cm^2$-kSZ^2 Cross Correlation

Mr. Clinton Denis Stevens, Prof. Yin-Zhe Ma

Stellenbosch University

Abstract

The Hydrogen Epoch of Reionization Array (HERA) upon completion will be a 350-element Radio Interferometer, consisting of 14 m parabolic dishes operating in the low-frequency range (50-250 MHz). HERA aims to achieve the first detection of the 21cm power spectrum during the Epoch of Reionization (z = 6-12). During the Epoch of Reionization (EoR), radiation from the first stellar populations causes fluctuations in the 21cm brightness temperature. By successfully measuring the 21cm power spectrum, the Astrophysics underlying the EoR may be constrained. These Astrophysical constraints include the timing and efficiency of reionization, as well as the star-formation and halo properties of the first galaxies (Berkhout et al., 2024). Previous EoR 21cm mapping experiments suffer from residual foreground noise and systematic uncertainties (La Plante et al., 2020). Therefore, we propose a new cross-correlation technique involving the squared 21cm intensity field and the squared kinematic Sunyaev-Zeldovich (kSZ) effect. We present our novel $<\delta T_{21cm}^2 \Delta T_{kSZ}^2>$ cross-correlation technique and forecast signal-to-noise estimates for future experiments. In particular, cross-correlation experiments with the South Pole Telescope (SPT) and the Next Generation CMB Experiment (CMB-S4).

Bispectrum correlations of HI intensity mapping and large-scale structure surveys

Dr Moumita Aich

University of KwaZulu-Natal

Abstract

Neutral hydrogen (HI) intensity mapping (IM) experiments probe the large-scale structure of the universe through the integrated redshifted 21-cm line emission from unresolved sources of neutral hydrogen. Optical surveys also probe the large-scale structure of the universe with much higher precision and depth by mapping the galaxy distribution. In this article, we study the cross-correlations of the HI IM field from HIRAX (Hydrogen Intensity and Real-time Analysis eXperiment) with the galaxy density and cosmic shear fields from the Rubin observatory large-scale structure survey, laying down the tools to do parameter forecasts and study constraints on the neutral hydrogen fraction, galaxy bias, and cosmological parameters. Astrophysical foregrounds limit the long-wavelength line-of-sight HI modes, reducing the constraining power of these cross-correlations. We introduce bispectrum estimators, specifically HI-HI-galaxy density and HI-HI-shear cross bispectra estimators, to recover modes lost in the foreground subtraction process and improve the parameter constraints.

Cosmic Web: Influence of Tidal Anisotropy in the formation of Galaxies and Haloes

M. Sc. Yeimy Camargo, Dr. Rigoberto Casas-Miranda

Universidad Nacional de Colombia

Abstract

The observed galaxy distribution beyond halo scale is organised into a filamentary network known as the cosmic web. In this work we explore the influence of the cosmic web on the formation of halos and galaxies by examining the tidal anisotropy, estimated using the *NEXUS* algorithm and data from *The Next Generation Illustris simulations (IllustrisTNG)*. Specifically, we use galaxies and dark matter haloes from the simulation labelled as *TNG300-1*, focusing on galaxies with stellar masses in the range of $10^9 < M_*(M_{sun}/h) < 10^{11.5}$ and their host dark matter haloes. For this purpose, we used the assembly times of the dark matter haloes, as well as the assembly times, star formation efficiency F_*, colour (g-i), and specific Star Formation Rate sSFR of both central and satellite galaxies. In each case, the samples are separated in several sets: early and late assembly time, low and high F_*, red and blue (g-i) colour, and low and high sSFR. We aim to understand the relationship between the cosmic web environment and some characteristics related to the formation and evolution of DM haloes and galaxies.

Statistical Modelling and Mitigation of Systematics in 21-cm Radio Observation Experiments

Mr Geoff Murphy

University of the Western Cape

Abstract

In the current era of cutting-edge radio astronomy, instruments are becoming ever more sensitive to the highly-redshifted 21-cm signal, and as a consequence are suffering from more numerous systematics which inhibit their performance. While many systematic mitigation methods are capable of recovering signals down to the noise level, statistical modelling of these systematics can produce equivalent results with the addition of uncertainties rigorously propagated throughout the analysis. In this talk, we demonstrate the application of Hamiltonian Monte Carlo sampling to the signal chain systematics in the Hydrogen Epoch of Reionisation Array (HERA), namely cable reflections and antenna coupling. Recovery of the underlying power spectra can be made at a similar level to the methods currently implemented in the HERA pipeline, along with an associated uncertainty estimate, and without significant attenuation of the underlying signal. Additionally, we present results from the joint modelling of the signal, foregrounds, and systematics (RFI, cable reflections, and ground-spill) in MeerKAT datacubes on a per-antenna basis with Gibbs sampling, which allows the order 10^5-dimensional parameter space to remain computationally tractable. As radio experiments probe deeper into the Universe, and continue to place improved constraints on cosmological models, the addition of propagated statistical uncertainty estimates from the systematic mitigation steps would lend additional confidence to the upper limits on, and future direct detections of, faint 21-cm signals.

The VLA Sky Survey

Mark Lacy

National Radio Astronomy Observatory

Abstract

The VLA Sky Survey (VLASS) images all the sky visible to the VLA in multiple epochs at 2-4 GHz. VLASS is the highest-resolution all-sky survey undertaken in the radio, with a typical beam size of 2.5 arcsec, comparable to ground-based optical/near-infrared (OIR) surveys. This allows unambiguous identifications of radio sources with OIR counterparts and separation of nuclear and off-nuclear radio transients in nearby galaxies. Since the beginning of the survey in 2017 VLASS has observed the sky twice, with a third epoch of observation near completion. Each epoch has a sensitivity of ~150 microJy/beam. Quick Look images are made available to the community within a few weeks of observation. Higher fidelity sets of images, which will also include spectral index and polarization information, are in progress. I will give an overview of the survey and present some the early results, including detections of radio-bright extragalactic supernovae, tidal disruption events and radio changing-look AGN.

Star formation rate and stellar mass calibrations based on JWST and WISE infrared photometry and the biases from stellar population age and extinction

Dr. Konstantinos Kouroumpatzakis[1], Prof. Andreas` Zezas[2,3,4], Mr. Elias Kyritisis[2,3], Prof. Samir Salim[5], Dr. Jiri Svoboda[1]

[1]Astronomical Institute of the Czech Academy of Sciences. [2]University of Crete. [3]Institute of Astrophysics/FORTH. [4]Center for Astrophysics | Harvard & Smithsonian. [5]Indiana University

Abstract

Measuring accurately the fundamental properties of stellar mass (M⋆) and star formation rate (SFR) is critical for understanding the present state of galaxies, their history, and their future. This work explores the dependence of the IR emission of galaxies on their extinction, and star-formation intensity, and provides accurate calibrations that account for these effects. We used the CIGALE spectral energy distribution (SED) fitting code to create model SEDs of galaxies with a wide range of star formation histories, dust content, and interstellar medium properties. Results based on the Markov-chain Monte-Carlo method and machine-learning random forest analysis provide calibrations for the SFR using a combination of the WISE 1 and 3, or the JWST NIR-F200W and MIRI-F2100W bands. Mass-to-light ratio calibrations are also proposed based on the WISE band-1 or the JWST NIR-F200W, and the optical u−r or g−r colors which account for biases attributed to stellar population (SP) age, while they are given in the form of extinction-dependent and extinction-independent relations. The proposed calibrations show enhanced estimations while minimizing the scatter and biases throughout a wide range of SFRs and stellar masses. The SFR calibrations offer better results, especially in dust-free or passive galaxies where the contributions of old SPs or biases from the lack of dust are significant. Similarly, the M⋆ calibration yields enhanced estimations for dusty and high-SFR galaxies where dust emission can otherwise bias the estimations.

Abstract

The Magellanic Bridge, a trail of stars and gas connecting the LMC and SMC, supposedly formed during the closest tidal interaction between them about 100-300 Myr ago. However, the origin and formation history of the Bridge are still poorly understood. We present the first-ever results on the Bridge using the Ultraviolet Imaging Telescope (UVIT) onboard AstroSat, the Indian space observatory to understand aforementioned aspects. The UVIT has a resolution of 1.2 arcsec (thrice better than GALEX) and a field of view of 28 arcmin, allowing an unprecedented view of the Bridge and individual stars in far-ultraviolet. Our UVIT observed fields combined with those from the archive (9 fields) span ~3° near the tidally disrupted SMC. These fields host UV bright star clusters and OB associations. We combined UVIT data with Gaia DR3 to estimate their parameters (age, distance, metallicity and extinction), by employing an automated fitting technique that uses a grid of these parameters and an MCMC sampling routine. About 80% of the clusters in these fields are parametrized for the first time, and we can dissociate clusters from OB-type associations. The study provides strong evidence that interactions between the LMC-SMC continued up to a few 10 Myr ago. We estimated the stellar (e.g. T_{eff} and log *g*) and kinematical properties of hot and young stellar populations by combining UVIT data with Gaia, VMC and other multiwavelength data sets. The results are significant in the context of understanding the structure, star formation history and metallicity of the Bridge, and the unique environmental conditions (low-gas density, low-metallicity, and tidally stripped) that could lead to the formation of OB-type stars.

Tracing the assembly history of the Local Group galaxies through long-period variable stars

Dr Atefeh Javadi

Institute for Research in Fundamental Sciences (IPM)

Abstract

The Local Group of galaxies represents the only group in which we have detailed knowledge of stellar populations, their formation, and evolution. As a result, we monitored a majority of galaxies in the Local Group at different wavelenghts, including the M33 galaxy and satellite galaxies surrounding the Milky Way and Andromeda galaxy in addition to isolated dwarf galaxies. Based on light curve analysis, we identified cool evolved stars pulsating in fundamental mode. Then, a novel technique developed by Javadi et al. 2011 was used to derive star formation history (SFH) using the luminosity of these cool-evolved stars. Through analyzing an entire satellite system, we determined how satellites vary as a result of infall histories, cosmic reionization, and internal processes. Then we gathered the multi-wavelength observations of LPVs to determine the mass-loss rates and dust production. In this paper, I will first present the results we obtained for SFH and dust production rate in individual galaxies separately so that we can understand how different types of galaxies have evolved over cosmic time. In the second part of my talk, I will discuss whether the mass return from dusty evolved stars can provide enough gas reservoirs to sustain star formation or even rejuvenate dwarf galaxies. In conclusion, I will compare the star formation histories of various types of galaxies found in different environments to gain a comprehensive understanding of galaxy evolution in the Local Group.

Studying the effect of physical parameters on galaxy classification using the concentration index tool.

Student Mary Ndimuwaki

Kenyatta university

Abstract

Our study explores how stellar mass, redshift, and environmental factors influence galaxy morphology through concentration index analysis. Using multi-wavelength data from optical and infrared surveys, we analyze galaxies across diverse redshifts and environments. Our findings reveal correlations between these parameters and morphological types.

Preliminary results suggest that galaxies with higher luminosities tend to exhibit higher concentration indices, indicating more centrally concentrated light profiles. Additionally, we observe subtle dependencies on stellar mass and environment, highlighting the complex interplay between intrinsic properties and environmental influences.

This research deepens our understanding of galaxy formation and evolution mechanisms by elucidating the role of specific physical parameters in shaping galactic morphology. These insights have significant implications for theoretical models in galaxy formation and contribute to a richer understanding of extragalactic astronomy.

Understanding the Galaxy-Halo connection: A perspective from the Mutual Information statistics

M.Sc. Yeimy Camargo, Dr. Rigoberto Casas-Miranda

Universidad Nacional de Colombia

Abstract

The galaxy-halo connection is a very active area of research in cosmology and it is crucial for understanding the galaxy formation and evolution. In this work we investigate the correlations between the assembly times of the dark matter haloes and the assembly times, star formation efficiency (F_*), color (g-i), and the specific Star Formation Rate (sSFR) of central and satellite galaxies. We use data of galaxies and dark matter haloes from the TNG300-1 simulation, which is part of The Next Generation Illustris simulations (IllustrisTNG). To quantify the correlations mentioned above, we compute the Mutual Information (MI) statistics on galaxies with stellar masses in the range of $10^9 \leq M\_\star(h^{-1}M_{sun}) \leq 10^{11.2}$ and their host dark matter haloes. The MI statistics reveals that the assembly times of galaxies and F_* are correlated with the assembly times of their host DM haloes for central galaxies with stellar masses below $M_* \cong 10^{10.25} h^{-1} M_{sun}$, whereas the color (g-i) and sSFR show a weaker correlation with the assembly times of their haloes. In the case of satellite galaxies the MI is close to zero across all stellar masses and quantities tested. The analysis of these results can be used to refine galaxy formation models.

An unusual, high-redshift, disk galaxy population discovered with JWST

Ms. Rashi Jain, Dr. Yogesh Wadadekar

NATIONAL CENTRE FOR RADIO ASTROPHYSICS - TATA INSTITUTE OF FUNDAMENTAL RESEARCH, INDIA

Abstract

We present a study on the morphological and global stellar population synthesis (SPS) properties of high-redshift galaxies within the redshift range of $3 < z < 6$. We use public JWST data from the UNCOVER survey, offering photometric redshifts and SPS properties derived via the photo-z code Prospector. We select a sample of 674 galaxies with SNR > 10 (in the F444w JWST/NIRCam filter) within the specified redshift range. We carry out visual morphological classifications by categorizing the sample into seven groups: disk only, spheroid only, irregular only, disk + spheroid, spheroid + irregular, disk + irregular, and disk + irregular + spheroid. We also derive non-parametric morphological classifications of the galaxies, calculating CASGM (Concentration, Asymmetry, Smoothness, Gini coefficient, M20) statistics. Our visual classifications reveal that 56% of galaxies in our sample contain a disk component, consistent with the disk fraction derived using CASGM statistics. We explore the correlations between morphologies and SPS properties of these high-redshift galaxies, noting that the majority of these galaxies are vigorously star-forming. We observe that disk galaxies dominate the more massive end of the population, and in the size-mass relation, disks exhibit larger sizes and greater masses. This result is surprising, as with previous studies done with HST, it was thought that most galaxies at high redshift are either spheroids or irregulars. Our findings align with similar other studies utilizing data from deep JWST surveys, such as CEERS and SMACS 0723.

Dusty star-forming galaxies as tracers of protoclusters: A simulated perspective

Pablo Araya Araya[1], Christopher Hayward[2], Rachel Cochrane[3,2], Laerte Sodré Jr.[1], Robert Yates[4], Douglas Rennehan[2], Roderik Overzier[5], Marcelo Vicentin[1]

[1]Universidade de São Paulo. [2]Flatiron Institute (CCA). [3]Columbia University. [4]University of Hertfordshire. [5]Observatório Nacional

Abstract

Dusty star-forming galaxies (DSFGs) are commonly used as tracers of galaxy protoclusters, withmany spectacular examples identified with telescopes such as the South Pole Telescope, Planck, andHerschel. However, to date, there has been relatively little 'first principles' theoretical work that modelsthe connection between DSFGs and protoclusters. To address this gap, we have incorporated scalingrelations (derived in previous work by performing radiative transfer calculations on hydro simulations)to predict far-IR/submm flux densities into the L-Galaxies semi-analytic model. I will present a fewresults from this new model. Specifically, I will show that protocluster cores exhibit an excess of DSFGsrelative to protocluster 'outskirts' and the field. However, contrary to some claims in the literature, thisis not due to the dense environment 'triggering' starbursts. Rather, the DSFGs typically lie near the starformation main sequence. The reason for the excess is that protocluster cores have an excess of massivegalaxies relative to less-overdense regions. Moreover, the model predicts that the brightest DSFGs arepredominantly located in protocluster cores.

The LOFAR Two-metre Sky Survey: The Nature of the Faint Source Population and SFR-Radio Luminosity Relation using Prospector

Mr Soumyadeep Das

University of Hertfordshire

Abstract

Spectral energy distribution (SED) fitting has been extensively used to determine the nature of the faint radio source population. Recent efforts have combined fits from multiple SED-fitting codes to account for the host galaxy and any active nucleus that may be present. We show that it is possible to produce similar-quality classifications using a single energy-balance SED fitting code, Prospector, to model up to 26 bands of UV - far-infrared aperture-matched photometry for over 31000 sources in the ELAIS-N1 field from the LOFAR Two-Metre Sky Survey (LoTSS) Deep fields first data release. One of a new generation of SED-fitting codes, Prospector accounts for potential contributions from radiative active galactic nuclei (AGN) when estimating galaxy properties, including star formation rates (SFRs) derived using non-parametric star formation histories. Combining this information with radio luminosities, we classify 92 per cent of the radio sources as a star-forming galaxy, high/low-excitation radio galaxy, or radio-quiet AGN and study the population demographics as a function of 150 MHz flux density, luminosity, SFR, stellar mass, redshift and apparent r-band magnitude. Finally, we investigate the SFR--150 MHz luminosity relation for a sample of 133000 3.6 micron-selected z<1 sources, finding that the stellar mass dependence is significantly weaker than previously reported, and may disappear altogether at moderate to high SFR regimes. This study makes it significantly easier to classify forthcoming radio source samples from LoTSS and elsewhere, and have important implications for upcoming radio frequency studies of star-forming galaxies.

Formation and evolution of the Nuclear Star Cluster in the Milky Way and other spiral galaxies on the cosmological time scale

Prof. Dr. Sci. Peter Berczik, Dr. Marina Ishchenko, Ms. Margarita Sobolenko

Main Astronomical Observatory National Academy of Sciences of Ukraine, 27 Akademika Zabolotnoho St. 03143 Kyiv, Ukraine

Abstract

According to the standard LCDM model, the globular clusters (GCs) of the Milky Way (MW) are the first gravitationally bound stellar systems to form in the early Universe, with a typical age of about 10-12 billion years. GCs are quite common in the Galaxy. In early 2020, 150 of them were found in the MW, in 2022 - 160, and more than 10 stellar systems are candidates for GCs. In the past few years, we have been getting more and more direct evidence for the existence of a supermassive black hole (SMBH) at the center of the MW and other galaxies. In addition to the SMBH, the Nuclear Star Cluster (NSC) is also located in the center of the Galaxy. Several mechanisms have been proposed for the formation of such NSCs. Two main ones are distinguished: (i) the migration of gas into the center of the Galaxy and the subsequent formation of the stellar content of the NSCs, and (ii) the migration of GCs into the center of the Galaxy and their subsequent destruction and total or partial merging with the compact central NSCs. The goal of our study is to numerically model the formation of NSCs by the dynamical interaction of GCs with the central region of the MW and other spiral galaxies (e.g., Andromeda), including the strong interaction with the central SMBHs. Based on the numerical calculations performed, qualitative estimates of the probabilities of complete and partial absorption of individual GCs in different orbits will be given.

Deconvolving photometric redshifts: Using machine learning to obtain the large-scale structure from photometric data

Mr. Erik Lima, Prof. Dr. Laerte Sodré

Instituto de Astronomia, Geofísica e Ciências Atmosféricas da Universidade de São Paulo

Abstract

The determination of galactic distances, derived from the redshift of their spectral features, is of fundamental importance for several astronomical investigations, spanning from the identification of local universe structures to cosmological studies. However, this approach presents several challenges since the time required to obtain reliable spectra increases exponentially, specially at fainter magnitudes. In the age of very large surveys able to probe several millions or billions of objects, this approach becomes infeasible. Therefore a different methology is required.

This alternative method leverages the large amount of photometric data that the aforementioned surveys will provide, allowing the estimation of photometric redshifts. However, although faster to obtain, their lower precision can lead to biases that can be hard to address, limiting their application in some fields of study.

In this work we take advantage of the accurate photometric redshifts from the Southern Local Universe Survey and develop a machine learning model with the goal of deconvolving these estimates providing a new, less noisy photometric redshift, which enables us to recover the structures in the local universe with good precision (10% lower scatter and 3 times less bias) using exclusively photometric data. With this we will also present an analysis of the physical properties of galaxies in the Stripe-82 region and their connection to the different environments, giving insights into their formation and evolution.

The results of this work can be applied to other surveys, allowing for a better utilization of their scientific potential specially in the context of large-scale structure studies.

Environmental effects on subhalo masses of satellite galaxies in galaxy clusters

Mr . Amit Kumar[1], Prof. Surhud More[1,2], Dr. Tomomi Sunayama[3], Dr. Divya Rana[4]

[1]Inter University Center for Astronomy and Astrophysics, Pune (India). [2]Kavli Institute for the Physics and Mathematics of the Universe, Japan. [3]Steward Observatory, University of Arizona. [4]Leiden Observatory

Abstract

We investigate the matter distribution around satellite galaxies evolving in dense galaxy clusters, using the weak gravitational lensing technique; leveraging Year-1 public data from the Hyper Suprime Cam survey. We explore the effect of environment specific processes on the dark matter mass around SDSS redMaPPer satellites, by comparing it to the distribution around a control sample of galaxies matched to satellites in photometric properties but residing in a non-cluster environment. In order to understand the impact of host potential on the subhalo mass of the satellite, we bin satellite galaxies as a function of projected separation from the cluster centre. We see hints of a difference in the subhalo mass of satellites compared to the halo masses of galaxies in our control sample, especially in the innermost cluster-centric radial bin ($0.1 < R < 0.3$ h^{-1}Mpc). We use these measurements to put a first-ever direct upper limit on the prevalence of galaxies that have lost their subhalo entirely, i.e. orphan galaxies, at different distances from the cluster center. We confront a leading galaxy formation model, i.e. UniverseMachine to these observational constraints on the prevalence of orphan galaxies. We find the fraction of orphan galaxies invoked by the UniverseMachine is marginally consistent with these observational upper limits in the innermost regions of galaxy clusters and significantly higher in the outer regions of galaxy clusters particularly beyond 0.3 h^{-1}Mpc. We also discuss ways to distinguish any physical effects that could result in orphan galaxies from any numerical effects in the empirical model.

Abstract

The Subaru Hyper Suprime-Cam (HSC) survey is the deepest amongst the ongoing Stage 3 weak gravitational lensing surveys. Using data from the Year 3 (Y3) release of the shapes of galaxies, we have performed three blinded cosmology analyses to measure the amplitude of fluctuations in the late Universe. The tomographic cosmic shear analyses were carried out in both real and Fourier space. A 3x2 point analysis, which combines the cosmic shear with the clustering and galaxy-galaxy lensing signal of galaxies from a combination of the HSC data with spectroscopic galaxy samples from the SDSS, was also performed in order to obtain cosmological constraints. These analyses utilize more than 25 million galaxies in the HSC-Y3 catalogs in four tomographic redshift bins ranging from 0.3 to 1.5 and over the survey area of 416 sq. degrees. Applying wide and conservative uninformative priors on the photometric redshift errors, for a flat LCDM model, we obtain values of S8=0.767+0.031-0.034 (68% C.I.), a 4 percent error with the real space cosmic shear analyses. The rest of the analyses also result in values for S8 which are internally consistent with this number. A comparison of our result in the context of the LCDM model with the Planck 2018 cosmic microwave background observations shows consistency albeit a ~2 sigma lower value for the parameter S8. We identify the inference of the redshifts of the photometric source galaxies to be the largest contribution to the systematic uncertainty budget and comment on possible ways to empirically address it.

A Plausible Solution to the Hubble Tension *via* Cosmologically Varying Fundamental Natural Constants

Professor Golden Gadzirayi Nyambuya

National University of Science and Technology

Abstract

A number of scientists have wondered if the Hubble tension heralds some *hitherto* yet unknown physics or there might be some serious error in our methods and analysis? For a plausible solution, we suggest a cosmologically varying Planck constant --- *i.e.*, a Planck constant that varies in proportion to the cosmic expansion scale factor. This cosmologically varying Planck constant introduces a new correction term to the distance modulus. When the new corrected distance modulus term is applied to the Union2.1 dataset of 580 type Ia supernovae which typically yield: $H_0 \sim$ 70-to-76 km/s/Mpc, we obtain a 99.49% (*i.e.*, R^2-value) fit between the proposed theory and the Union2.1 dataset of 580 SNe Ia and this impressive fit-to-data yields: $H_0 = 68.70 \pm 0.30$ km/s/Mpc. We consider our result to be in good agreement with that obtained by the Planck collaboration, thus, the tension in the two values may have found a solution worthy to be taken seriously. If acceptable, this solution somewhat forces physicists to the drawing board to re-consider and take much more seriously the idea of variable Fundamental Natural Constants (FNCs) as this phenomenon may introduce `*dark*' effects which may be interpreted as darkenergy or darkmatter.

X-shaped sources in the MeerKAT + South Pole Telescope 100 square-degree survey at 816 MHz

Mr William Rasakanya

University of the Witwatersrand

Abstract

X-shaped Radio Galaxies (XRGs) exhibit rare, exotic morphologies with two pairs of radio lobes with an offset jet axis. Their formation remains an open question, with a wide range of proposed models, including reoriented radio jet axes due to black hole spin-flips following a binary black hole merger, hydrodynamical backflows, and overpressurised lobes, amongst others. A large, uniformly selected sample of X-shaped sources mapped with high-image fidelity is an important step towards understanding the relative presence of an XRG sample in the MeerKAT + South Pole Telescope 100 square-degree survey at 816 MHz. To date, five sources that fit the description have been found in approximately half the data, highlighting the rarity of these objects. We present a multiwavelength analysis of these sources, including sub-arcsecond Dark Energy Survey multi-band optical imaging. Uniform studies of XRGs from wide-area surveys such as this will help us understand the various formation models of XRGs, improve 3D GRMHD simulations, and refine our understanding of radio galaxy formation, including the role of their environment.

Training Models of Type Ia Supernovae for the Next Generation of Cosmology Surveys

Kene Anumba[1], Dr. Maria Vincenzi[1], Prof. Daniel Scolnic[1], Prof. David Jones[2]

[1]Duke University. [2]University of Hawai'i

Abstract

In the next few years, a new generation of supernova surveys will begin, including the Legacy Survey of Space and Time (LSST) and the Nancy Grace Roman Space Telescope surveys. These surveys will help discover up to a million supernovae, orders of magnitude beyond what has been discovered so far. To use Type Ia Supernovae (SNe Ia) to constrain cosmological parameters like the equation-of-state of dark energy, one must establish a spectro-photometric model of the supernova explosion time series. The accuracy of the model itself may be one of the limiting systematic uncertainties of any cosmological inference. Here, we use new simulations of the LSST and Roman survey to train a light-curve model. We show in this poster the accuracy and precision of this model over the range of wavelengths that these surveys will probe, from the optical to the near-infrared. We present a first look at how changing certain parts of the observing strategy of these surveys can change the precision of the trained models. Finally, we explain how to reproduce this work and use our trained models in forecasting the cosmological constraints of this next generation of surveys.

Probing Late-Time Anisotropies With Weak-Lensing

Mr James Adam

University of the Western Cape

Abstract

One of the cornerstones of the standard model of cosmology is the assumption that, on sufficiently large scales, the Universe is homogeneous and isotropic. Some dark energy and modified gravity models, however, naturally lead to large-scale anisotropies. Thus, it is of great importance to test this broad assumption. One possible method of probing these anisotropies involves the use of weak gravitational lensing. More specifically, the imprints that these anisotropies would have on the weak shear of light beams on cosmological scales could be analysed in upcoming surveys like Euclid, SKA, and LSST.

The Atacama Cosmology Telescope: Galactic Dust Structure and the Cosmic PAH Background in Cross-correlation with WISE

Rodrigo Córdova-Rosado[1], Brandon Hensley[1,2], Susan Clark[3,4], Adriaan Duivenvoorden[5], Jo Dunkley[6,1], The Atacama Cosmology Telescope Collaboration[6]

[1]Department of Astrophysical Sciences, Princeton University, Princeton, NJ, USA. [2]Jet Propulsion Laboratory, California Institute of Technology, Pasadena, CA, USA. [3]Department of Physics, Stanford University, Stanford, CA, USA. [4]Kavli Institute for Particle Astrophysics & Cosmology, Stanford University, Stanford, CA, USA. [5]Center for Computational Astrophysics, Flatiron Institute, New York, NY, USA. [6]Joseph Henry Laboratories of Physics, Jadwin Hall, Princeton University, Princeton, NJ, USA

Abstract

We present a cross-correlation analysis between 1′ resolution total intensity and polarization observations from the Atacama Cosmology Telescope (ACT) at 150 and 220 GHz and 15″ mid-infrared photometry from the Wide-field Infrared Survey Explorer (WISE) over 107 12.5∘×12.5∘ patches of sky. We detect a spatially isotropic signal in the WISE×ACT TT cross power spectrum at 30σ significance that we interpret as the correlation between the cosmic infrared background at ACT frequencies and polycyclic aromatic hydrocarbon (PAH) emission from galaxies in WISE, i.e., the cosmic PAH background. Within the Milky Way, the Galactic dust TT spectra are generally well-described by power laws in ℓ over the range $10^3<\ell<10^4$, but there is evidence both for variability in the power law index and for non-power law behavior in some regions. We measure a positive correlation between WISE total intensity and ACT E-mode polarization at $1000<\ell\lesssim6000$ at >3σ in each of 35 distinct ∼100 deg^2 regions of the sky, suggesting alignment between Galactic density structures and the local magnetic field persists to sub-parsec physical scales in these regions. The distribution of TE amplitudes in this ℓ range across all 107 regions is biased to positive values, while there is no evidence for such a bias in the TB spectra. This work constitutes the highest-ℓ measurements of the Galactic dust TE spectrum to date and indicates that cross-correlation with high-resolution mid-infrared measurements of dust emission is a promising tool for constraining the spatial statistics of dust emission at millimeter wavelengths.

Narrow-band photometric selection of quasars with large-sky surveys (S-PLUS)

Lilianne Nakazono, Raquel Ruiz Valença, Prof. Claudia Mendes de Oliveira

Universidade de Sao Paulo

Abstract

Quasars are among the most luminous sources in the Universe and are found at a wide range of redshift up to z ~ 7.6. However, most of the confirmed quasars are in the northern hemisphere and the number decreases drastically in the southern hemisphere. Enlarging the sample of confirmed quasars at a wide range of masses and luminosities will improve our understanding of the large-scale structure and the underlying physical processes surrounding the supermassive blackholes. The Southern Photometric Local Universe (S-PLUS) will cover ~9300 square degrees of the southern sky with an 80-cm telescope located in the Cerro Tololo Inter-American Observatory. The observations are taken in 12 optical bands: 5 sloan-like broad bands and 7 narrow bands centered in stellar features. Currently, S-PLUS is the survey that has released data for the largest area of the southern sky (~3000 square degrees in DR4) with the highest number of narrow bands, hence S-PLUS is a great laboratory for evaluating the importance of narrow-band information in machine learning using real data. We show in our work that the narrow-band photometry increases the performance of star/galaxy/quasar classification (Nakazono et al. 2021) and photometric redshift estimation (Nakazono & Valença, submitted) compared to broad-band models, even when also considering infrared data. In this talk, I will present these works in detail and our publicly-available quasar photometric catalog for S-PLUS DR4 that contains >600k high-probability candidates. Finally, I will discuss our prospects of using these photometrically selected quasars for studying large-scale structures.

Title: A search for relics and halos associated with SZ-selected clusters in the wide-field MeerKAT + South Pole Telescope Survey

Mr Isaac Magolego

University of the Witwatersrand

Abstract

Galaxy clusters are the largest gravitationally bound objects in the universe. They serve as important astrophysical laboratories and cosmological probes when used on a statistical basis. Here we present first results from the MeerKAT UHF band (544–1087 MHz) search for radio halos and relics in the South Pole Telescope discovered SZ-selected cluster sample. The homogeneously mass-selected cluster sample is therefore complemented by deep (~10 uJy/beam), high fidelity, uniform sensitivity imaging at 816 MHz, leveraging MeerKAT high survey speed at this frequency. Expanding statistical samples into these broader ranges will enhance our comprehension of the life cycle of widespread radio emission in clusters. This, in turn, will allow us to enhance existing models of particle reacceleration and potentially suggest adjustments should our observations unveil previously undiscovered behaviours.

Unveiling high-redshift quasars with anomaly detection techniques in S-PLUS

Raquel Ruiz Valença, Lilianne Nakazono, Prof. Claudia Mendes de Oliveira

Instituto de Astronomia, Geofísica e Ciências Atmosféricas da Universidade de São Paulo

Abstract

The search for quasars at high redshifts has become an increasingly relevant topic. Studying these objects, especially the more luminous ones, contributes to research on the accretion physics of supermassive black holes, the evolution of galaxies, and the large-scale structure in the early epochs of the Universe. As the number of known quasars declines sharply past z~3.5 (Lyke et al., 2020), high redshift (z>5) quasars can be considered as rare objects, so in this project we apply anomaly detection techniques in order to find high redshift quasars in the Southern Photometric Local Universe Survey (S-PLUS). S-PLUS, with its extensive photometric coverage (~3000 square degrees with S-PLUS DR4), serves as an ideal laboratory for identifying these rare objects, enabling effective photometric selection for subsequent spectroscopic follow-up. To find such quasars, we will use the photometric information contained in the 5 broad bands and 7 narrow bands from S-PLUS, along with the photometry from the WISE survey. Moreover, we will study how the photometric redshifts we estimate (Nakazono & Valença et al., submitted) for S-PLUS quasar candidates can assist us in anomaly detection. We have compared color-color diagrams of our quasar candidates with quasars confirmed by spectroscopy and found that a 3-dimensional diagram including the S-PLUS u, g, and J0861 bands and both WISE W1 and W2 bands provides a good selection of high redshift quasars. Additionally, we have applied dimensionality reduction techniques (e.g. t-SNE) and machine learning methods, such as Isolation Forest, to refine this analysis.

The Early and Fast Settlement of Milky Way Disk

Lais Borbolato[1], Hélio Perottoni[2], Silvia Rossi[1], Guilherme Limberg[1], João Amarante[3], Cristina Chiappini[4], Anna Queiroz[4]

[1]Universidade de São Paulo. [2]Laboratório Nacional de Astrofísica. [3]Universitat de Barcelona. [4]Leibniz Institute for Astrophysics Potsdam

Abstract

The Milky Way (MW) has historically served as a template for understanding the formation and evolution of massive late-type disk galaxies in general. The combination between astrometric data from Gaia mission and spectroscopic surveys have allowed us to map the entire history of our Galaxy, from a turbulent proto-MW at early times to the barred spiral that we see today. This transformation from a dynamically hot proto-MW to its present-day dynamically cold state is marked by a "spin-up" transition when in-situ stars quickly gain angular momentum, hence rotation. Using metallicities as a proxy for time, previous studies found that this spin-up phase occurs at about [Fe/H] ~ -1.2. However, because metallicity is not directly correlated with age and accurate stellar ages are difficult to estimate, we still haven't been able to directly time the spin-up. In this work, we applied the spectro-photometric code StarHorse to obtain ages for a large sample of stars from SEGUE and LAMOST catalogs. For the first time, we demonstrate that the spin-up starts at 11.5 Gyr in the past and last for just 2 Gyr. We also investigate the behavior of the thin and thick disks during this phase as well as how the halo responds to it. In the near future, this result will be compared to MW analogs found in galaxy formation simulations for us to advance our knowledge regarding the physical processes that control the establishment of galaxy disks across cosmic time.

Emission line properties of type-2 AGN in theLockman-SpReSo survey

Mrs Bereket Assefa, Professor Mirjana Povic

Space Science and Geospatial Institute, Addis Ababa, Ethiopia

Abstract

Active galactic nuclei (AGN) are some of the brightest sources in the Universe, emitting light at all wavelengths due to their complex structure. Deep multi-wavelength extra-galactic surveys are therefore important for understanding the full physics of AGN and their role in the formation and evolution of galaxies. The Lockman-SpReSo survey is one of the deepest multi-wavelength spectroscopic surveys in the optical and far-infrared (FIR), obtained using the GTC 10 m and Herschel telescopes, respectively. Using this survey, we selected an unique sample of type-2 AGN in the FIR with deep optical spectroscopic data to study the relationship between their fundamental properties in the FIR and in the optical. Specifically, in this work we aim to better understand the optical spectroscopic properties of type-2 FIR AGN by characterizing the emission line properties and comparing them with the FIR properties. In this talk, we will present the analyses performed on the identification and characterization of the emission lines and the various spectroscopic and IR properties of selected type-2 AGN.

Star Formation and Gas Supply in the Green Valley Over Cosmic Time

Kyle Cook, Dr Benne Holwerda, Clayton Robinson

University of Louisville

Abstract

The green valley and its role as a transitional space for quenching or rejuvenation of star formation remains a heavily researched topic in galaxy evolution. Early evidence suggests an evolution in the relationship between HI mass and star formation rate over cosmic time. The Looking At the Distant Universe with the MeerKAT Array (LADUMA) survey aims to produce the deepest direct detections of HI, allowing for our most complete view of this relationship. We analyze a small sample of galaxies in the LADUMA L-Band selected for existing Spectral Energy Distribution (SED) fit results and NUV data (Swift or XMM). These galaxies have low HI fractions, which we interpret as the result of recent quenching and possible rejuvenation. We present our multi-year plan to take advantage of the excellent synergy of the LADUMA data with upcoming instruments such as Rubin Observatory and the Euclid and Roman Space Telescopes.

Searching for radio halos in edge-on starburst galaxies

Camila Galante[1,2], Dr. Juliana Saponara[1,2], Dr. Gustavo Romero[1,2], Dr. Paula Benaglia[1]

[1]Argentine Institute for Radioastronomy (IAR). [2]National University of La Plata (UNLP)

Abstract

Starburst galaxies undergo intense episodes of star formation that cause gas to be ejected by winds into the galaxy's surroundings. Strong shocks, capable of accelerating cosmic rays, can form when these winds interact with the intergalactic medium. At radio wavelengths, the radiation from the cosmic rays can be detected as a halo, which can be characterized by a scale height. How these halos relate to the global properties of the galaxies can help to understand the origin of the halo and the underlying cosmic ray population. Here we present our search for the presence of radio halos in a sample of 25 edge-on starburst galaxies from the MeerKAT 1.28 GHz Atlas of Southern Sources in the IRAS Revised Bright Galaxy Sample. We detected 11 radio halos, seven of which are reported for the first time. The dependence of the halo luminosities on the star formation rate and the infrared luminosities we found support the hypothesis that the radio halos are the result of synchrotron radiation produced by relativistic electrons. To explain the average scale height of 1 kpc that we found, there must be some process that reaccelerates cosmic rays in the halo, if gamma ray emission of leptonic origin is detected from the halo. From our sample, the galaxy NGC 4666 is a potential gamma ray source for future observations, according to the radio and gamma ray luminosity relation.

The evolution of the M - Lx relation in the CODEX galaxy cluster sample

Isabel Pederneiras[1], Prof.Dr. Eduardo Cypriano[1], Prof.Dr. Alexis Finoguenov[2]

[1]Institute of Astronomy, Geophysics and Atmospheric Sciences, R. do Matão, Butantã, São Paulo, Brazil. [2]Department of Physics, University of Helsinki, Helsinki, Finland

Abstract

Precise measurements of X-ray scaling relations in galaxy clusters are imperative to probe cosmological parameters. The functional form of the correlation between X-ray luminosity and the mass of clusters is established in the purely gravitational self-similar model. However, deviations become apparent when non-gravitational processes, e.g. radiative cooling and AGN feedback, exert influence, potentially leading to a temporal evolution of the relation.

Up until this work, precise calibration of the M-Lx relation and its evolution, employing weak-lensing mass estimates and a consistent statistical methodology, was still lacking. Our calibration utilizes the CODEX catalog, constructed by an X-ray and optical selection of clusters in the superposition area of RASS and SDSS surveys. We analyze 101 CODEX galaxy clusters with weak-lensing masses, which is considered to be a less biased mass proxy.

Introducing a Bayesian hierarchical model, we account for measurement errors, intrinsic scatter, selection functions, and the subsample's construction criteria. The CODEX weak-lensing sample is well fit by a power law in log space with a slope of 0.3 ± 0.05, which is significantly shallower than the self-similar prediction. We also report an evolution parameter of 1.54 ± 0.55, which is statistically significant to infer a positive evolution of the scaling relation. As we investigate these intriguing findings, we point out our distinctive statistical approach and our analysis focused on a high-mass sample as potential factors. We also conjecture the effects of AGN feedback and a possible evolution bias due to our Lx distribution.

Galaxy-Cluster Membership Assignment Using High-Precision Photometric Redshifts

Elismar Lösch, Dr. Laerte Sodré

Instituto de Astronomia, Geofísica e Ciências Atmosféricas - Universidade de São Paulo

Abstract

In the study of galaxies in large scale structures, such as groups and clusters, one of the fundamental steps is to reliably dictate which galaxies belong to a given structure of interest. Leveraging the high-precision photometric redshifts (photo-zs) acquired from the Southern Photometric Local Universe Survey (S-PLUS), we explore different approaches to identify galaxies potentially belonging to groups and clusters of galaxies.

Typically, the determination of galaxy memberships in clusters and other structures relies on spectroscopic redshifts. However, the cost of extensive spectroscopic observations and the absence of a comprehensive survey in the southern hemisphere has restricted these observations to only the brightest galaxies. To address this limitation, we utilize photometric redshifts to refine membership assignments in the southern hemisphere structures.

Our approach incorporates the development and implementation of two distinct galaxy-cluster membership methods. The first method employs a sigma-clipping technique, taking into account the typical photo-z uncertainty as a function of galaxy magnitude to identify cluster members. This method has been applied to select targets for observation within CHANCES, the CHileAN Cluster galaxy Evolution Survey. The second method employs a robust Bayesian approach to assign membership probabilities to galaxies in clusters. We have successfully tested this method in cluster mocks and applied it to the two richest clusters of the Hydra Supercluster of galaxies: Hydra (Abell 1060) and Antlia (Abell S0636). We achieved the promising values of 92% and 81% for completeness and 68% and 81% for purity for Hydra and Antlia respectively.

A FRESH LOOK AT GALAXY SCALING RELATIONS AND WHAT THEY REVEAL ABOUT GALAXY FORMATION

Michael Fall[1], Enrico Di Teodoro[2], Lorenzo Posti[3]

[1]Johns Hopkins University. [2]University of Florence. [3]Observatory of Strasbourg

Abstract

Despite the apparent complexity of galaxies, some of their most basic properties (mass M, binding energy E, angular momentum J, etc) obey simple power-law scaling relations. Such relations provide some of the clearest insights into galaxy formation. This talk focuses on the relations between circular velocity V (a proxy for specific energy, $e = E / M$ proptoV^2) and mass M and between specific angular momentum $j = J / M$ and M. The observed forms of these scaling relations for the stellar components of galaxies, M_s propto V_s^4 and j_s propto $M_s^{0.6}$, are closely linked to the corresponding relations for their dark halos in CDM-type cosmologies, M_h propto V_h^3 and j_h propto $M_h^{2/3}$. We have obtained new kinematic (Ha and HI) and photometric data that extend the relations for late-type galaxies (spirals and irregulars) over the full range of stellar masses: $M_s \sim 10^8$ to $\sim 10^{12}$ M_{sun}. From the same data, we derive the "retention factors" for mass $f_M = M_s / M_h$ (aka stellar-to-halo mass ratio, SHMR) and specific angular momentum $f_j = j_s / j_h$, finding f_M propto $M_s^{0.4}$ and $f_j \sim 1$ independent of M_s. In contrast, for the most massive early-types galaxies (ellipticals and lenticulars), f_M declines with M_s and $f_j << 1$. We draw some simple but important conclusions from these empirical results about the physical origins of several basic properties of galaxies, including their sizes, compositions (stars vs gas), morphologies (disk vs spheroid), and feedback drivers (stars vs AGN). We also show that the observed forms of f_M and f_j are reproduced in contemporary cosmological hydrodynamical simulations of galaxy formation (IllustrisTNG).

Cosmology from Cluster Structure

Prof. James Taylor

Waterloo Centre for Astrophysics. University of Waterloo

Abstract

The abundance of galaxy clusters in the low-redshift universe provides a classic cosmological test, constraining a product of the matter density Ω_m and the amplitude of fluctuations parameter σ_8. Unfortunately, the test has a strong degeneracy between these two parameters, allowing a range of different cosmological models for any given abundance measurement. We propose a new test, based on the internal structure and accretion rate onto clusters, that breaks this degeneracy, and can significantly improve the resulting constraints. We illustrate the potential of the new test using lensing data from the UNIONs imaging survey, and compare our results to recent abundance constraints from eROSITA.

[4]Department of Physics and Astronomy, University of Manitoba, Winnipeg, Manitoba R3T 2N2, Canada. [5]Dept of Physics and Astronomy at McMaster University, Canada

Abstract

We present high-resolution MeerKAT radio continuum images of star-forming spirals in the nearby galaxy groups NGC 6221, NGC 3263 and NGC 2434. This sample spans the evolutionary timeline for galaxy groups, encompassing early, intermediate, and late stages, respectively. The NGC 6221 group contains a pair-wise interacting galaxy with tidal debris along with a few dwarf galaxies, while the NGC 3256 group represents a loose group where members are pre-processing via pair-wise interactions as they begin to fall towards the group's centre of mass. The NGC 2434 group has an elliptical galaxy, and the other group members appear to be accreting onto this central object. Since star formation (SF) is one of the dominant physical processes in the formation and evolution of galaxies, we study the SF activity in the group members. Specifically we seek evidence of environmental impact on SF. We use MeerKAT observations and archival infrared WISE data to measure the amount and location of SF activity. Also, spectral index maps, created by employing the in-band method, provide insights into the underlying physical processes associated with the observed star-forming regions. Additionally, we examine two galaxies in detail. NGC 6215 has a peculiar velocity field, which may be explained by accreted bridge material settling into a plane offset from the spiral disc. NGC 3263 has a highly inclined disk and extended tidal tail containing radio continuum emission. For NGC 3263, sensitive radio continuum observations are crucial to thoroughly trace and characterize its vertically extended radio halo for the first time.

Understanding the role of environment on the quenching of the star formation: a multi-dimensional minefield

Luca Cortese[1], Barbara Catinella[1], Rory Smith[2]

[1]ICRAR-UWA. [2]Federico Santa María Technical University

Abstract

One of the key open questions in extragalactic astronomy is what stops star formation in galaxies, and whether the environment a galaxy inhabits matters. Throughout the decades, an incredibly large array of observational studies have quantified the variation of star formation (and other galaxy properties) with environment in fine detail. While these studies started by focusing on the cluster vs. field dichotomy, we are now at the stage where we are able to trace the multi-dimensionality of the concept of environment by taking into account the position of galaxies within bound structures and within filaments. In this work, I will review the status of environmental studies on galaxy quenching in the local Universe from an observational perspective. I will show that, while it is clear that the different external processes affect the gas-star formation cycle of galaxies in different environments, quantifying their role on the quenching of star formation across the full range of dark matter halos and stellar masses remains a complex task, as different physical mechanisms may act simultaneously and cannot always be easily separated. Despite these challenges, I will also argue that we are making progress and we are gradually building a coherent framework on how and when environment matters for galaxies quenching. I will conclude by highlighting several outstanding questions where we expect to see substantial progress in the coming decades, thanks to the advent of the Square Kilometre Array and its precursors.

A study of extreme CIII]1908 and [OIII]88/[CII]157 emission in Pox 186 in Pox 186: Implications for JWST+ALMA (FUV+FIR) studies of distant galaxies

Dr Nimisha Kumari[1], Dr Renske Smit[2], Dr Claus Leitherer[1], Dr Joris Witstok[3], Dr Mike Irwin[3], Dr Marco Sirianni[1], Dr Alessandra Aloisi[1]

[1]Space Telescope Science Institute. [2]Liverpool John Moores University, UK. [3]University of Cambridge, UK

Abstract

Carbon spectral features are ubiquitous in the ultraviolet (UV) and far-infrared (FIR) spectra of the reionization-era galaxies. We probe the ionized carbon content of a dwarf galaxy Pox 186 using the UV, optical, mid-infrared and FIR data taken with Hubble, Gemini, Spitzer and Herschel, respectively. This local ($z\sim0.0040705$) galaxy is likely an analogue of reionization-era galaxies, as revealed by its extreme FIR emission line ratio, [O iii]88 μm/[C ii] 157 μm (>10). The UV spectra reveal extreme C iii]$\lambda\lambda$ 1907, 1909 emission with the strongest equivalent width (EW) = 35.85 ± 0.73 Å detected so far in the local ($z\sim0$) Universe, a relatively strong C iv$\lambda\lambda$ 1548, 1550 emission with EW = 7.95 ±0.45Å, but no He iiλ 1640 detection. Several scenarios are explored to explain the high EW of carbon lines, including high effective temperature, high carbon-to-oxygen ratio, slope and upper mass of top-heavy initial mass function, hard ionizing radiation and in-homogeneous dust distribution. Both C iii] and C iv line profiles are broadened with respect to the Oiii]λ 1660 emission line. Each emission line of Civ$\lambda\lambda$ 1548, 1550 shows the most distinct double-peak structure ever detected, which we model via two scenarios, firstly a double-peaked profile that might emerge from resonant scattering and secondly, a single nebular emission line along with a weaker interstellar absorption. The study demonstrates that galaxies with extreme FIR properties may also show extreme UV properties, hence paving a promising avenue of using FIR+UV in the local (via Hubble+Herschel/SOFIA) and distant (via JWST+ALMA) Universe for unveiling the mysteries of the reionization-era.

Outflows from Stellar Feedback in the Early Universe

Mr James Nianias

The University of Hong Kong

Abstract

Outflows powered by feedback from star formation are believed to suppress the buildup of stellar mass in galaxies throughout cosmic history. However, definitive observational evidence for such outflows in the early universe has proven to be elusive. Here, we present investigations of two very different outflow signatures at high redshifts. Our first study targets ionized/atomic outflows from some of the lowest-mass galaxies known. We analyse the spectra of ~ 600 gravitationally-lensed Lyman-α emitters at z ~ 2.9 – 6.7 in which metal lines are seen in emission and – in some cases – also in absorption. We find the Lyman-α spectral profiles to be consistent with models of expanding shells of partially-neutral gas. Where detected, the absorption lines are blueshifted relative to the systemic velocity of the host galaxy as measured by the metal emission lines, providing unambiguous evidence of outflows. In our second study, we search for signatures of outflows of molecular gas from dusty star-forming galaxies at z ~ 4 – 6, which, if detected, would constitute clear evidence of star-forming material being driven out of the galactic disc. Such outflows have previously been inferred from OH absorption that is blueshifted compared to [CII] emission, with the latter being attributed to interstellar gas in the disc. Here, we reanalyse these observations, showing that most of the purported OH absorption signatures are not statistically significant. On the other hand, we demonstrate a more rigorous procedure to search for blueshifted OH absorption, finding tentative evidence of outflows in all of the five sources examined.

Identification of lopsided galaxies using Convolutional Neural Network

Mr. Biju Saha[1], Dr. Arunima Banerjee[1], Dr. Suman Sarkar[2], Mr. Ganesh Narayanan[1]

[1]Indian Institute of Science Education and Research (IISER), Tirupati. [2]Indian Institute of Technology (IIT), Kharagpur

Abstract

The non-axisymmetric features in disc galaxies including bars and spiral arms are fundamentally important in driving their secular evolution. Yet another promiscuous non-axisymmetric feature in the galactic disc is the large-scale asymmetry in the distribution of stars and gas, commonly referred to as lopsidedness. However, their formation and evolution are not very well understood. Quantitatively, lopsidedness is the normalised amplitude of the non-zero m=1 mode in the Fourier decomposition of the surface brightness distribution of the galaxy. About 30 % of the galactic disc shows global lopsidedness. In this work, we aim to augment their relatively sparse sample size by new identifications from the updated catalogs from the more recent surveys, using machine learning methods. To implement the same, we train the publicly-available ALEXNET, a convolutional neural network model for binary classification of galaxies into lopsided and non-lopsided galaxies. For training the neural network, we selected 50 galaxies images from the Sloan Digital Sky Survey Data Release 12 from Bournaud et al., 2005. After deprojecting the galaxy images to face-on view, we obtained the value of for each galaxy. Based upon the above-calculated value of and the threshold well-adopted in the literature, we labelled the galaxies as lopsided and not lopsided. Our trained model achieved an accuracy of almost 90 % on the validation set. We aim to further improve our testing accuracy by expanding the training set for our model, allowing the model to learn more efficiently.

Extended Blazar Sequence for γ-ray Emitting Active Galactic Nuclei

Dr Finbarr Odo, Dr Akagu Audu, Dr Evaristus Iyida, Professor Augustine Ubachukwu

University of Nigeria, Nsukka

Abstract

In this paper, we use the distributions of observed γ-ray properties, as well as orientation parameters of a sample of *Fermi*-LAT AGNs to investigate the hypothesis that γ-NLS1 objects are beamed sources with γ-ray emitting axes inclined at close angles to the line of sight. Based on these parameters we investigate the relationship between γ-NLS1s and other subclasses of γ-ray emitting jetted AGNs. Results show that γ-NLS1s are more highly beamed than both FSRQs and BL Lacs with mean value of core-dominance parameter R_g ~ 9507. γ-NLS1s and jetted Seyfert galaxies are continuous in distribution of the orientation parameter with average cone angles Φ_m ~ 8° and 44° respectively. Furthermore, the spectral energy distribution of γ-NLS1 is comparable to those of FSRQs and BL Lacs suggestive that γ-NLS1s and blazars form a continuous spectral sequence. There is a significant anti-correlation (r ~ -0.9) between the γ-ray dominance (D_g) and γ-ray luminosity. There is a strong dependence of D_g on redshift (r ~ -0.7) suggestive that D_g is more sensitive to environmental factors than intrinsic γ-ray luminosity. The results suggest that γ-NLS1s are highly beamed γ-ray sources whose de-beamed counterparts can be found among Seyfert galaxy populations.

Detection of an extreme high ionization emission line FeX from Lyalpha emitter

Dr Abhishek Paswan

University of Allahabad, Prayagraj

Abstract

We report the first detection of an extreme high-ionization potential (262.1 eV) emission line [Fe {\sc x}] λ6374 in the spectrum of a Lyman-α emitter (LAE), SHOC 579 at $z \sim 0.047$. This detection is subsequently followed by the presence of optical nebular He{\sc ii} λ4686 emission line, {\sc x}-ray ($0.5 - 8$ kev) and 1.4-GHz radio continuum emissions. We diagnose the origin of all these emissions using the standard characteristic relation of star-forming galaxies such as radio-far-infrared correlation and {\sc x}-ray luminosity relative to star formation rate and gas-phase metallicty. These relations do not exhibit any evidence of active galactic nuclei activity, and support the fact that the above detected emissions most likely originated due to the recent starburst event in the LAE. Our results in this study conclude that such objects in the early Universe might have played a crucial role in the re-ionization of Hydrogen by leaking their ionizing radiations. However, the leakage of these ionizing radiations additionally depends on the inter-stellar medium structure of the galaxy.

The relation between the growth of the bulge and the galaxy quenching at low redshifts.

Monyke Hellen dos Santos Fonseca[1], Paulo Afrânio Lopes[2], André Ribeiro[3]

[1]Federal University of Rio de Janeiro. [2]Federal Univeristy of Rio de Janeiro. [3]Santa Cruz State University

Abstract

Galaxy structure is one of the fundamental ways by which galaxy properties are described and by which galaxy evolution is inferred. Evidence suggests that more massive galaxies tend to have their star formation rates suppressed earlier in the Universe. On the other hand, environmental density also plays a critical role, with galaxies in denser environments showing higher quenching rates. There is currently a debate in the literature about how the growth of bulges relates to the decline in the star formation rate. In this sense, for sample selection we match data from SDSS, KIAS, MPA-JHU and GALEX, with $0.03 < z < 0.1$, TType < 0 , absolute magnitude ≤ -20.5 and color gradient < 1. Our objective is to characterize the bulge's structures in order to establish which mechanisms may have recently contributed to its current constitution, restricting the relationship between quenching and galaxy morphology. To characterize the bulge, we carry out a Principal Component Analysis (PCA) analysis taking into account morphometric parameters such as the CASGM system, environmental variable $\Sigma 5$, and spectral variables such as $H\alpha$, $H\delta$ and D4000 lines, to analyze star formation. We know that different processes can be associated with different quenching time scales, which can be distinguished between fast (< 300Myr) and slow (1Gyr) processes, therefore, we use the Starpy code to estimate the time from which the process started of quenching in galaxies, and the speed at which the process occurred.

Hunting for primordial black holes using lensing parallax of GRBs

Ms Priyanka Gawade[1], Dr Surhud More[2,3], Dr Varun Bhalerao[4]

[1]Inter-University Centre for Astronomy and Astrophysics, Ganeshkhind, Pune 411007, India. [2]Inter-University Centre for Astronomy and Astrophysics, Ganeshkhind, Pune 411007, IN. [3]Kavli Institute for the Physics and Mathematics of the Universe (WPI), University of Tokyo, 5-1-5, Kashiwanoha, 2778583, Japan. [4]Department of Physics, Indian Institute of Technology Bombay, Powai, Mumbai, 400076, India

Abstract

Nature of the dark matter has always been an important unresolved mystery. Primordial black holes, which could have formed during the early Universe through overdensities in primordial density fluctuations during inflation, are potential candidates for dark matter. Various experiments have already ruled out a vast parameter range for the possible masses of such primordial black holes. However, there exists a window in the mass range $[10^{-16}-10^{-11}]M_\odot$ where such PBHs remain unexplored thus far. We explore the use of lensing parallax of Gamma ray bursts (GRBs), which results in different fluxes being observed from two different vantage points, in order to probe the abundance of primordial black holes in this unexplored mass range. We derive the optical depth for the lensing of GRBs with a distribution of source properties and realistic detector sensitivities. We comment on the ability of the proposed Indian twin satellite mission Daksha in its low earth orbit to conduct this experiment. If the two Daksha satellites observe 10000 GRBs simultaneously and the entirety of dark matter is made up of $[10^{-15}-10^{-12}]M_\odot$ black holes, Daksha will detect non-zero lensing events with a probability ranging from 80 to 50 per cent at the bin edges, respectively. Non-detections will not conclusively rule out primordial black holes as dark matter in this mass range. However, we show that meaningful constraints can be obtained in such a case if the two satellites are separated by at least the Earth-Moon distance.

New frontiers in cosmology with Cosmic Microwave Background polarization surveys

Professor Erminia Calabrese

Cardiff University

Abstract

The Cosmic Microwave Background (CMB) is a unique probe to study the physics of the Universe. This light, travelling since ~380,000 years after the Big Bang, contains relic signatures of the physical processes that took place at the origin of the Universe, as well as unique features allowing us to determine precisely the abundances of the main Universe constituents which govern its evolution on large scales.

During the last three decades, the astonishing agreement between CMB theory and increasingly-precise observations has led to the establishment of our standard model of cosmology. While the parameters of this model have been constrained to sub-percent precision, many fundamental questions about the Universe are still unanswered. In the near future, a series of ground-based and satellite experiments promise to deliver new breakthroughs in cosmology and fundamental physics via precise measurements of the CMB polarization signal. For example, CMB polarization at high resolution is sensitive to any new physics that changes the Universe's thermal history or energy budget, degree-scale polarization is instead the route to detect primordial gravitational waves.

In this talk I will give a snapshot of where we are in CMB cosmology, how we got here and where we are heading next. I will cover in particular the upcoming Simons Observatory (SO) experiment which is starting operations in 2024. SO will provide the most sensitive microwave maps over more than 50% of the sky, with observations overlapping and taking place concurrently with major surveys in other wavelengths such as Rubin and Euclid.

Mini merger or big accretion? Asymmetry and star-formation in low-mass collisions.

Dr. Connor Bottrell

ICRAR/UWA

Abstract

Asymmetry is ubiquitous in the structures of star forming galaxies (SFGs) in the nearby Universe. However, the origin of this asymmetry is uncertain. An important clue comes from the observed relationship between galaxy asymmetries and star formation rates (SFRs). But what mechanisms are responsible for this connection? Both external gas accretion and galaxy-galaxy mergers are invoked as plausible options. Using the TNG50 simulations and mock Subaru Telescope images, I show that major and minor mergers (mass ratios > 1:10) cannot explain the variety in asymmetries for local SFGs. Their incompatibility is due to the long timescales between major/minor merger events and their short-lived (albeit high amplitude) effects on asymmetries and SFRs. In contrast, mini mergers (mass ratios 1:10 to 1:100) appear as inconspicuous but important drivers. According to TNG50, individual mini mergers yield “mini” enhancements in asymmetries and SFRs that persist on longer timescales than the average time between mini merger events. Consequently, asymmetric structure and SFEs aggregate via mini mergers. According to these results with TNG50, 70% of asymmetric structure and 55% of in-situ stars formed in mergers specifically originate from mini mergers. Are these mini collisions driving star-formation via gravitational torques? Or are they simply entrained in large scale gas inflows?

Discovery of a grand design spiral galaxy at the redshift of z~4.

Ms. RASHI JAIN, Dr. YOGESH WADADEKAR

NATIONAL CENTRE FOR RADIO ASTROPHYSICS - TATA INSTITUTE OF FUNDAMENTAL RESEARCH, INDIA

Abstract

We present the discovery of a huge (∼10 kpc) and two-armed grand-design spiral galaxy at the redshift of approximately 3.8 through JWST. Utilizing publicly available JWST data from the UNCOVER survey we identify the photometric redshift to be 3.79 and 3.78, derived via stellar population synthesis (SPS) modeling codes Prospector and EAZY respectively. To mitigate the high error bars in the UNCOVER photometric redshifts, we cross-verify the redshift using SED modeling with an independent SED modeling code, Bagpipes. We fit exponential and delayed exponential parametric star formation histories to the observed SED and derive joint constraints on the photometric redshifts and SPS parameters. We determine the photometric redshift to be $3.82^{+0.2}_{-0.05}$. Our modeling with Bagpipes reveals that this is a huge, massive ($\log M_{\odot} = 10.37^{+0.02}_{-0.01}$) and a highly star-forming spiral galaxy (SFR of $67.6^{+11.8}_{-10.1}$ $M_{\odot}yr^{-1}$), consistent with UNCOVER catalog results. Furthermore, the detection in UNCOVER ALMA band 6 (1.2 mm) observations reveals an integrated flux density of approximately 1 mJy in ALMA band 6 which allows us to get the SFR estimate in FIR. The SFR calculated using the FIR ALMA flux of this galaxy is ∼90 $M_{\odot}yr^{-1}$, similar to the SFR derived from SED modeling. We emphasize that this is an HST dark galaxy with a knotty structure in the optical rest-frame indicating its star-forming regions and a bright central core. The formation of spiral arms so early in the universe is bizarre, these spiral arms might be transient and have been formed by a recently completed galaxy merger.

Unusual metallicity gradient and star formation efficiency in the giant low surface brightness galaxy Malin 1

Dr. Junais Junais

National Centre for Nuclear Research (NCBJ), Warsaw, Poland

Abstract

Giant low-surface brightness (GLSB) galaxies are an extreme class of objects with very faint and extended gas-rich disks. Malin 1 is the largest GLSB galaxy known to date, but its formation is still poorly understood. We use VLT/MUSE IFU spectroscopic observations of Malin 1 to reveal, for the first time, the presence of H-alpha emission distributed across numerous regions along its disk, up to radial distances of about 100 kpc. We observe a steep decline in the star formation rate surface density within the inner 20 kpc, followed by a shallow decline in the extended disk. Similarly, the gas phase metallicity we estimated shows a steep gradient in the inner 20 kpc, followed by a flattening of the metallicity in the extended disk with a relatively high value of about 0.6 solar. Such a flattening provides clues on the formation of its disk. We found that the accretion of pre-enriched gas from a past merger is the most likely scenario for its formation. A comparison of the star formation rate surface density and gas surface density shows that Malin 1 exhibits a very low star formation efficiency (about 2 orders of magnitude lower than normal spirals), indicating a break in the well-known Kennicutt-Schmidt relationship at the LSB regime. Our findings contribute to a more detailed understanding of the formation of the giant disk of Malin 1 and also constrain possible proposed scenarios on the nature of GLSB galaxies in general.

Foreground hardened quadratic estimator for CMB weak lensing convergence reconstruction

Mr. Kishan Deka

National Center for Nuclear Research, Warsaw, Poland

Abstract

Cosmic Microwave Background (CMB) photons experience weak gravitational lensing due to the large-scale structure of the Universe along their path. The weak lensing generates a divergence-free component of the polarization field known as B-modes, through the gravitational lensing of the primordial curl-free component of the field, known as E-modes. Estimating the lensing power spectra and delensing the CMB maps from recent and upcoming surveys are crucial tasks for the advancement of observational cosmology. However, one of the main obstacles to these tasks is the presence of foreground contamination in the CMB maps. In the era of high-sensitivity CMB experiments, the bias in delensing arising from these sources may exceed the statistical uncertainties of the observational data. Our objective is to study the efficiency of different lensing estimators in the context of upcoming CMB surveys and then provide new methods to mitigate the biases in lensing reconstruction. In our work, we test polarization-based quadratic estimators on simulated lensed CMB maps with instrumental properties corresponding to the CMB-S4 survey. Here, we present the foreground bias in quadratic estimators on simulated maps contaminated by galactic emissions. We also present impact of point source radio galaxies in polarisation based lensing reconstruction estimators. Foreground immune lensing methods for reducing extragalactic point source contamination has already been studied in literature. We extend on these works to mitigate galactic foreground contaminations. In our work, we present how impact of residual galactic foreground bias after component separation can be reduced for full-sky lensing reconstruction.

The Star Formation History in Local Group Galaxies

Dr. Yi Ren[1], Prof. Biwei Jiang[2,3], Dr. Yuxi Wang[1], Dr. Ming Yang[4], Dr. Zhiqiang Yan[5]

[1]Department of Astronomy, College of Physics and Electronic Engineering, Qilu Normal University. [2]Institute for Frontiers in Astronomy and Astrophysics, Beijing Normal University. [3]Department of Astronomy, Beijing Normal University. [4]Key Laboratory of Space Astronomy and Technology, National Astronomical Observatories, Chinese Academy of Sciences. [5]Key Laboratory of Modern Astronomy and Astrophysics (Nanjing University), Ministry of Education

Abstract

The star formation histories (SFHs) of galaxies provide valuable insights into galaxy evolution and stellar physics. Understanding the SFHs enables the study of chemical enrichment of galaxies, star formation triggered by interactions, and the behavior of various stellar populations. This work investigates the SFHs of M31, M33 and ten dwarf galaxies in the Local Group (LG), which spans a wide range of types, masses, luminosities, and metallicities. The analysis is based on our new sample of the member stars in the LG after removing the foreground dwarf stars by the near-infrared color-color diagram and the Gaia astrometric information. The samples include the most complete and pure red supergiants and asymptotic giant branch stars to gain valuable insights into the recent SFHs of the galaxies. The Padova isochrones are used to generate initial model CMDs, accounting for photometric errors and completeness through star field simulations to match the completeness and error distributions of the observed CMDs. Subsequently, the SFHs, distance modulus, and metallicity of the twelve galaxies are determined by fitting the CMDs. The SFH maps of M31 and M33 are obtained. Furthermore, this work shows that the star formation activity in dwarf ellipticals persisted up to 30 Myr ago. A significant increasing feature in the SFH of NGC 6822 reveals star formation activity triggered by an interaction event.

A novel analysis of contamination in Lyman break galaxy samples based on spatial cross-correlation with intermediate-redshift galaxies

Miftahul Hilmi[1,2], Dr Nicha Leethochawalit[3], Prof Michele Trenti[1,2], Benjamin Metha[1,2]

[1]School of Physics, the University of Melbourne. [2]ARC Centre of Excellence for All Sky Astrophysics in 3 Dimensions (ASTRO 3D). [3]National Astronomical Research Institute of Thailand (NARIT)

Abstract

Potential contamination from low/intermediate-redshift galaxies, such as objects with a prominent Balmer break, affects the photometric selection of high-redshift galaxies through identification of a Lyman break. Traditionally, contamination is estimated from spectroscopic follow-up and/or simulations. Here, we introduce a novel approach to estimating contamination for Lyman-break galaxy (LBG) samples based on measuring spatial correlation with the parent population of lower redshift interlopers. We propose two conceptual approaches applicable to different survey strategies: a single large contiguous field and a survey consisting of multiple independent lines of sight. For a large single field, we compute the cross-correlation function between galaxies at redshift $z \sim 6$ and intermediate-redshift galaxies at $z \sim 1.3$. We apply the method to the CANDELS GOODS-S and XDF surveys and compare the measurement with simulated mock observations, finding that the contamination level in both cases is not measurable and lies below 5.5% (at 90% confidence). For random-pointing multiple field surveys, we measure instead the number count correlation between high-redshift galaxies and interlopers, as a two-point correlation analysis is not generally feasible. We show an application to the LBG samples at $z \sim 8$ and the possible interloper population at $z \sim 2$ in the Brightest of Reionizing Galaxies (BoRG) survey. By comparing the Pearson correlation coefficient with the result from Monte Carlo simulations, we estimate a contamination fraction of 62^{+13}_{-39}%, consistent with previous literature. These results validate the proposed approach and demonstrate its utility as an independent check of contamination in photometrically selected samples of high-redshift galaxies.

Developments in extragalactic astronomy in East Africa

Dr. Mirjana Povic

Space Science and Geospatial Institute, Ethiopia

Abstract

In recent years, East Africa has emerged as a region contributing to the study of galaxies. Several countries in the region started from scratch by providing the first postgraduate training in galaxy formation and evolution, training the first Master and PhD students in extragalactic astronomy, creating the first intra-African research groups and collaborations, and coming up with the first peer-reviewed publications in the field. In particular, strong collaborations have been established between Ethiopia, Rwanda, Uganda and Tanzania, in collaboration with South Africa and Botswana, and strong international collaborations outside Africa. Our research focuses, through different projects, on the properties of AGN and their host galaxies, on the study of the role of AGN in quenching star formation, on the properties of green valley galaxies, and on the properties of galaxies in galaxy clusters. This talk will be a journey through the development of extragalactic astronomy in East Africa, highlighting the major achievements of our scientific research, human capacity building and collaborative initiatives. It will also highlight many of the challenges we have faced on this journey and the opportunities for fostering a vibrant and growing research community in the region.

X-ray properties of high-z dust-obscured galaxies in the deep extragalactic fields

Dr Abhijit Kayal, Dr Veeresh Singh

Physical Research Laboratory, Ahmedabad, India

Abstract

In pursuit of exploring high-z obscured AGN population hosted in DOGs and their evolutionary scenario, we conducted an X-ray spectral study of 34 relatively X-ray bright high-z ($0.59 \leq z \leq 4.65$) DOGs, lying within 5.3 deg^2 of the XMM-Spitzer Extragalactic Representative Volume Survey (XMM-SERVS) region in the XMM-LSS field. To improve the quality of the X-ray spectra of individual sources, we combined all the existing XMM-Newton data and Chandra/ACIS data, whenever available. By fitting the X-ray spectra with both a simple absorbed power law and a torus-based borus02 model, we derived the line-of-sight column density ($N_{H,\,LOS}$) for all DOGs. Notably, our study identified three new Compton-Thick (CT)-AGN candidates hosted in DOGs, with a substantial fraction (08/34 $\simeq$ 23.5 per cent) exhibiting heavy obscuration ($N_H > 10^{23}$ cm^{-2}). The remaining sources displayed only moderate obscuration (10^{22} $cm^{-2} \leq N_H \leq 10^{23}$ cm^{-2}). The absorption-corrected 2.0 − 10 keV luminosities of our X-ray detected sources (2.3×10^{43} erg s^{-1} to 6.3×10^{45} erg s^{-1}) suggested them to be luminous quasars. The N_H versus Eddington ratio diagnostic plot revealed that our DOGs represent a heterogeneous population belonging to different phases of AGN evolution. Only a few of our sample DOGs (around 12%) are found to be Hot DOGs, marked by peak accretion and obscuration, an indication of an early phase, while the remaining of our sources belong to intermediate or late phases where the radiative feedback from the AGN likely to blow away the obscuring material.

Can two-temperature treatments in GRMHD simulations reduce the disparity between model and data variability for Sgr A*?

Leon Salas[1], Koushik Chatterjee[2], Gibwa Musoke[3], Sera Markoff[1], Bart Ripperda[3], Matthew Liska[1]

[1]Anton Pannekoek Institute for Astronomy, University of Amsterdam. [2]Institute for Research in Electronics and Applied Physics, University of Maryland. [3]Canadian Institute for Theoretical Astrophysics, University of Toronto

Abstract

In 2017, the Event Horizon Telescope Collaboration (EHTC) observed the Galactic center source SgrA* and found a ring-like structure consistent with expectations from general relativity. The EHTC "fiducial" models to describe these data are based on single-particle (assumed to be ions) fluid general relativistic magnetohydrodynamic (GRMHD) simulations. The ion/electron temperature ratio is modelled based on the local magnetization of the plasma, where the predicted emission is strongly dependent on these models. The two most promising models are magnetically arrested disks (MADs), however these and nearly all other models fail to reproduce SgrA*'s light-curve variability at 230 GHz. Moreover, no model successfully passes all the variability and multiwavelength constraints together.

The actual temperature ratio depends on microphysical dissipation and radiative processes not captured in ideal fluid simulations. Therefore, we investigate the effects of two-temperature thermodynamics of a MAD around SgrA*, where the temperatures of both species are evolved more self-consistently. We include Coulomb coupling, radiative cooling of electrons, and mimic heating of electrons via magnetic reconnection. The inclusion of two-temperature treatment, variable adiabatic index, and cooling in MAD GRMHD simulations reduce the 230 GHz light curve variability compared to single-temperature simulations. Yet, historical observations of SgrA* still show lower variability than simulations. Even for the very low accretion rates relevant for SgrA*, we find that radiative cooling still affects the accretion flow, lowering the electron temperature in the inner disk and reducing the average 230 GHz flux.

The dust attenuation-inclination relation for 13 000 bulges and discs in nine bands

Dr. Sarah Casura

Universität Hamburg

Abstract

Dust and inclination effects severely change the observed properties of galaxies. The choice of dust model and correction method thus has a strong influence on the inferred physical properties of galaxies such as intrinsic UV and optical flux, star formation rate, star formation history, metallicity evolution or stellar mass.

I will present the first results of our ongoing long-term project to constrain the nature and distribution of dust in galaxy discs with a comprehensive approach in which attenuation properties are compared to all other fundamental properties of galaxies for a well-characterised, statistically large and representative sample of galaxies.

To this end, we have performed bulge-disc decompositions of a sample of 13 096 local ($z < 0.08$) galaxies from the highly complete Galaxy and Mass Assembly (GAMA) galaxy redshift survey, with imaging data in nine bands spanning the optical and NIR (ugriZYJHKs). Combining this catalogue with the UV, MIR and FIR imaging data from GAMA and the wealth of ancillary information (e.g. on the environment and gas tracers) contained in value-added GAMA catalogues provides us with the means to perform a large statistical attenuation-inclination study with the most detailed set of data to date.

By comparing the distribution of galaxy components (bulges and discs) in the luminosity - size plane as a function of inclination and wavelength with the corresponding predictions made by the detailed radiative transfer models of Tuffs & Popescu, we are able to constrain the dust properties of our sample of galaxies.

Turbulent Magnetic Field Amplification and Cosmic Ray Propagation in Galaxy Clusters

Stela Adduci Faria[1], Prof. Elisabete de Gouveia Dal Pino[1], Prof. Reinaldo Santos-Lima[1], Rafael Alves Batista[2]

[1]Instituto de Astronomia, Geofísica e Ciências Atmosféricas - USP. [2]Sorbonne Université, Institut d'Astrophysique de Paris

Abstract

Magnetic fields play a crucial role in the complex dynamics of galaxy clusters. In our research, We focus on understanding the amplification of these fields by employing a turbulent dynamo in a weakly collisional and viscous intra-cluster environment. The plasma in the IntraCluster Medium (ICM) deviates from local thermodynamic equilibrium, making it susceptible to kinetic instabilities which introduce effective collisionality. This regulates anisotropy and allows for the stretching and amplification of the magnetic fields through small-scale turbulent dynamo. We utilize high-resolution weakly collisional three-dimensional magnetohydrodynamic simulations (3D MHD), incorporating for the first time a self-consistent evolution of the viscosity coefficient. This approach results in a smaller viscous coefficient which extends the inertial range of the ICM turbulent spectrum to the observed viscous scales in clusters, as in Coma. We also explore cosmic ray (CR) propagation performing Monte Carlo simulations in a highly resolved (≈ 4 kpcs) cosmological MHD simulation of a cluster with magnetic fields evolved by turbulent dynamo. We inject CRs with energies in the range 10^{14} to 10^{19} eV, and follow their cascading over the entire cluster obtaining precisely their gamma ray and neutrino fluxes. This implies important constraints on the determination of the dark matter counterpart through gamma-ray observations.

Post-planck appraisal of CMB Hemispherical Power Asymmetry

Mr. SANJEEV SANYAL, Dr. PAVAN KUMAR ALURI

INDIAN INSTITUTE OF TECHNOLOGY (BHU) VARANASI, INDIA

Abstract

In this work we present our analysis of one of the prominent "anomalies" of CMB sky, the "hemispherical power asymmetry (HPA)", from the latest fullsky CMB maps from Planck satellite mission's Public Release 4. The data is analyzed from various perspectives to understand the nature of HPA better viz., a re-estimation of the magnitude and direction of HPA and the corresponding significance, any frequency dependence of HPA, consistency of the recovered amplitude and direction across data sets from Planck as well as WMAP. We do so using the Local variance estimator (LVE), and also a new (modified) LVE which incorporates correlations between different patches of the sky from which local variances are computed. We find that the CMB hemispherical power asymmetry, phenomenologically modelled as a dipole modulation of an otherwise statistically isotropic CMB sky, is robust against all these tests and appears indeed to be a cosmic signal.

The impact of supernovae feedback on the metallicity gradients and mass-metallicity relations.

Dyna Ibrahim

University of Hertfordshire

Abstract

Metallicity is a fundamental physical property that strongly constrains galaxy formation and evolution. The formation of stars in galaxies is highly impacted by metal production and energy release from supernova explosions, which suppresses star formation by generating outflows and evaporating star-forming clouds. However, this process - supernova feedback - is uncertain. We thus include different feedback methods and parameters by ejecting energy in thermal, kinetic, stochastic and mechanical forms into our state-of-the-art cosmological simulations. Our code (based on Gadget-3) includes the latest nucleosynthesis yields for all stellar mass ranges, Type Ia supernovae, and also the first stars so that our predicted abundances are comparable to the observations of the first galaxies. For each feedback scheme, we predict the evolution of stellar mass-metallicity relations for stars and interstellar medium, as well as the metallicity gradients. We constrain the feedback method by comparing it with observational data from the James Web Space Telescope (JWST).

A MeerKAT 1.28 GHz continuum study of the Southern Sources in the IRAS Revised Bright Galaxy Sample

Ms Malebo Moloko

University of Cape Town

Abstract

The Infrared Astronomical Satellite (IRAS; Sanders et al. 2003) Revised Bright Galaxy Sample (RBGS) comprises galaxies and unresolved mergers with flux densities (S) > 5.24 Jy at λ= 60 μm and are extra-galactic (|b| > 5°). These are predominantly dusty star-forming galaxies. Previous studies in the nearby universe have revealed a tight correlation between infrared (IR)/radio emissions among such galaxies, making radio continuum emission an excellent complementary tracer of recent star formation. In this study, we examine the properties of 298 galaxies from RBGS in the southern hemisphere, observed at 1.28 GHz with MeerKAT (resolution 7.5''and σ ≈ 20 μJy/beam; Condon et al. 2021). We determine their activity types from the literature and classify them based on mid-IR information using WISE colour-colour diagnostics. We compare our findings with those of galaxies drawn from the same sample, albeit observed with VLA in the northern hemisphere (Condon et al.1990, 1996, 1998), thereby creating a full radio counterpart of the RBGS. In my contribution, I will discuss the samples' Infrared-radio correlation and the sources' physical properties (e.g., stellar masses, star-formation rates). Additionally, I will present insights gained from analyzing the interplay between AGN/SF mechanisms within these galaxies.

[4]Centre of Astrophysics Research, School of Physics, Astronomy and Mathematics, University of Hertfordshire, Hatfield, UK

Abstract

The Spitzer Survey of Stellar Structure in Galaxies (S4G) together with its Early Type Extension (ETG, Watkins et al. 2022) stands as the most extensive dataset of deep, uniform mid-infrared imaging for a sample of 2817 nearby (<40 Mpc) galaxies. The radio-derived velocity criteria, however, result in a sub-sample of 425 disk galaxies without 21cm HI detection but with optical velocities which satisfy the criteria. We present the Enhanced S4G (ES4G), a data set covering the set of 3242 galaxies within the original selection criteria. We collected archival 3.6 micron and i-band images and completed the data set with new observations for these missing disc galaxies. With this, we finish the survey, spanning a sample of 3242 galaxies with consistent imaging, surface brightness profiles and photometric parameters.

We produce masks, surface brightness profiles, and curves of growth and derive integrated quantities including total magnitudes, stellar masses, concentration parameters, and galaxy size metrics. We derive a recipe for the conversion between optical i-band and 3.6 micron. We present new morphological revised T-types and showcase mid-IR scaling relations among stellar mass, galaxy size, concentration index, and morphological type.

The full set of images, surface brightness profiles and derived parameters for the 3242 galaxies in the ES4G sample is made publicly available to the community. The ES4G will enable a wide set of investigations into galaxy structure and evolution, and complement optical and near-IR imaging to be obtained in coming years with Euclid, LSST and other projects.

An Euclid view of Globular Clusters of Dwarf Galaxies

Teymoor Saifollahi

Observatory of Strasbourg, France

Abstract

During its mission, Euclid will observe tens of thousands of dwarf galaxies in the Local Universe with fantastic depth and spatial resolution. Such a dataset enables us to identify Extragalactic Globular Clusters (EGCs) around these dwarf galaxies and gain unprecedented insight into their formation and evolution. In this talk, I present the analysis of Euclid data of EGCs around dwarf galaxies in two nearby galaxy clusters. This has been possible given Euclid's Early-Release Observations (EROs) of several nearby targets.

During the talk, I briefly introduce the adopted methodology for identifying EGCs (candidates) in Euclid VIS+NISP images to produce GC catalogues. Then, I study the GC properties of dwarf galaxies using the resulting GC catalogues. For that, I present the analysis of GC luminosity function, GC number counts and GC radial distribution around dwarf galaxies. At the end of this talk, I present the findings and briefly describe our plans within the Euclid consortium for studying EGCs around dwarf galaxies with the Euclid Wide Survey.

The work is done within the Euclid ERO teams and the Euclid consortium.

Unprecedented Insights from the stellar shells in nearby galaxies with SALT telescopes

Dr Adebusola Alabi, Prof. Ilani Loubser

North-West University, Potchefstroom

Abstract

In this talk, I will show recent results from the deep spectroscopy of the spectacular, faint, low surface brightness stellar features (shells) in the outskirts of NGC 2865. I will also show results from multi-object spectroscopy of the globular clusters that are spatially associated with these stellar shells. These data have been obtained recently from the SALT telescopes.

I will discuss how these data from the stellar shells and globular clusters help us constrain the nature of the merger event that produced these spectacular features and the nature of the disrupted progenitor. I will also discuss the implications of our results, i.e., the kinematics of multiple stellar shells in NGC 2865 and the stellar population properties (age, metallicity, star-formation histories) of these shells, in the context of expectations from recent cosmological simulations.

Application of anomaly detection to MeerKAT radio data using machine learning techniques

Dr. Hanwool Koo, Dr. Michelle Lochner

University of the Western Cape

Abstract

As a mid-frequency Square Kilometre Array precursor, the MeerKAT radio telescope is a promising source of large sets of radio data. Developing an automated method for anomaly detection is becoming essential to discover more unknown phenomena for astrophysics or cosmology from the data with such an enormous volume. To do this, we explore anomaly detection techniques for time-frequency dynamic spectra of the radio data. We apply unsupervised machine learning techniques, coupled with active learning, for anomaly detection and evaluate our method using the simulated Single-dish PARKES data sets for finding the uneXpected (SPARKESX). We use these simulations to test anomaly detection methods that will be applied to real, unlabeled MeerKAT data. We also examine the possibility of detecting and removing anomalous radio frequency interference, which acts as the primary contaminant when hunting for genuine anomalies. We expect that applying machine learning methods will be a more efficient and reliable way to detect anomalous astrophysical signals with higher accuracy and in a shorter time than the classical methods.

Shedding light on low-surface-brightness galaxies in dark energy surveys with transformer modelsShow affiliations

Mr Hareesh Thuruthipilly, Dr Junais Junais

National Center for Nuclear Research (NCBJ), Poland

Abstract

Low-surface-brightness galaxies (LSBGs), which are defined as galaxies that are fainter than the night sky, play a crucial role in our understanding of galaxy evolution and in cosmological models. Upcoming large-scale surveys, such as the Rubin Observatory Legacy Survey of Space and Time and Euclid, are expected to observe billions of astronomical objects. In this context, using semiautomatic methods to identify LSBGs would be a highly challenging and time-consuming process, and automated or machine learning-based methods are needed to overcome this challenge. We study the use of transformer models in separating LSBGs from artefacts in the data from the Dark Energy Survey (DES) Data Release 1. We created eight different transformer models and used an ensemble of these eight models to identify LSBGs.Transformer models achieved an accuracy of ~94% in separating the LSBGs from artefacts. In addition, we identified 4083 new LSBGs in DES, adding an additional ~17% to the LSBGs already known in DES. This also increased the number density of LSBGs in DES to 5.5 deg^{-2}. The new LSBG sample consists of mainly blue and compact galaxies. We performed a clustering analysis of the LSBGs in DES using an angular two-point auto-correlation function and found that LSBGs cluster more strongly than their high-surface-brightness counterparts. We associated 1310 LSBGs with galaxy clusters and identified 317 ultra-diffuse galaxies among them. The number of LSBGs is expected to increase with the advent of surveys with better image quality and more advanced methodologies.

PERTURBATION EFFECTS AND THE EVOLUTION OF GIANT LOW SURFACE BRIGHTNESS GALAXIES: THE CASE OF MALIN 1 - PAST AND FUTURE INTERACTIONS WITH SATELLITE GALAXIES

Student Ph. D. Roy Omar Edgar Bustos Espinoza[1,2,3,4,5,6], Dr. Gaspar Galaz[1], Dr. rer. nat. Matías Blaña[1]

[1]Astrophysics Institute, Pontificia Universidad Católica de Chile (PUC).. [2]Instituto de Investigaciones Físicas (IIF), Carrera de Física, Universidad Mayor de San Andrés (UMSA), La Paz, Bolivia.. [3]Sociedad Chilena de Astronomía (SOCHIAS).. [4]Asociación Boliviana para el Avance de la Ciencia (ABAC).. [5]American Astronomy Society (AAS).. [6]Sociedad Boliviana de Física (SOBOFI).

Abstract

Low surface brightness galaxies (LSBGs) dominate the volume density of galaxies in the universe; however, given their low surface brightness, are difficult to detect, introducing biases in the statistical analysis of galaxy populations. Giant low surface brightness disk galaxies (gLSBGs), on the other hand, have extended both neutral Hydrogen and its optical counterpart. One of the most impressive gLSBGs is *Malin 1*, given its 200 kpc stellar disk with giant spiral arms, a flat rotation curve, low star formation, low dust and a possible giant dark matter halo. Its environment shows at least two possible interacting galaxies, *exo-Malin 1* and *Malin 1B*, a gigantic stellar stream extending from *Malin 1* centre to a galaxy located to the NE, to the so-called galaxy *exo-Malin 1*. These features could be evidence of past or current perturbations in Malin 1.

We study the environment of the gLSBG *Malin 1* analysing the orbital history of its satellite galaxies by exploring possible close encounters in the past and in the future. We find orbits with trajectories that can connect the location of the satellite *exo-Malin 1* with an observed stellar stream candidate, which could indicate that *Malin 1* had a satellite interaction ∼2.25 Gyr ago; for *Malin 1B* case, ∼0.95 Gyr ago. For the future, ∼1.49 Gyr and ∼0.15 Gyr respectively.

This will allow us to model the internal and orbital evolutionary histories of *Malin 1* and its satellite candidates, allowing us to improve the galaxy formation and evolution models for gLSB galaxies in general.

KiDS-SBI: Simulation-Based Inference Analysis of KiDS-1000 Cosmic Shear

Dr Maximilian von Wietersheim-Kramsta[1,2], Dr Kiyam Lin[1], Dr Nicolas Tessore[1], Prof. Benjamin Joachimi[1], Dr Arthur Loureiro[3,4], Dr Robert Reischke[5,6], Dr Angus Wright[6]

[1]University College London. [2]Durham University. [3]Stockholm University. [4]Imperial College London. [5]Argelander-Institut für Astronomie. [6]Ruhr University Bochum

Abstract

Cosmic shear, the weak gravitational lensing effect on distant galaxies due to matter in the foreground, is a powerful tool to study the distribution of matter, to probe its large-scale structure, and infer the cosmological model of the Universe. Standard analyses are typically based on the assumption of a Gaussian likelihood with a parameter-independent covariance, but these assumptions may not always hold. Simulation-based inference (SBI) addresses this by evaluating an effective likelihood from forward-simulations which map parameters to data vectors. To this end, I will present a novel application of SBI to a cosmic shear analysis of the Kilo-Degree Survey's KiDS-1000 data release. The forward model is based on lognormal random fields which take into consideration systematics which are typically not modelled in standard inference. I will also describe how the simulated galaxy catalogues are compressed to shear-shear angular two-point statistics which are further compressed using score compression. I will show how we train a 12-dimensional neural likelihood estimation to obtain a converged and unbiased posterior of the cosmological parameters within ΛCDM. We find that our constraints on the weak lensing parameter, S_8, are similar to constraints from previous analyses of KiDS-1000. We note a non-negligible parameter-dependence in the learnt likelihood which is consistent with cosmic variance. At the same time, we find that systematics such as variable depth can have significant impacts on the posterior estimates. Lastly, I will highlight how these findings and SBI will help address the modelling/inference challenges facing upcoming stage IV galaxy surveys.

DES to HSC: Detecting LSBGs in Abell 194 with Transformers via Transfer Learning

Mr Hareesh Thuruthipilly, Dr Junais Junais

National Center for Nuclear Research (NCBJ), Poland

Abstract

Low surface brightness galaxies (LSBGs), characterized as galaxies fainter than the night sky, hold significant importance in comprehending galaxy evolution. The upcoming large-scale surveys such as the Rubin Observatory Legacy Survey of Space and Time (LSST) and Euclid are expected to uncover a large number of LSBGs which would require accurate automated methods for their detection. We study the scope of transfer learning for the identification of LSBGs in the Abell 194 cluster with the deep data we obtained from our Hyper Suprime-Cam (HSC) observations of this cluster. We use two ensemble of transformer models that have been trained on the dark energy survey data release 1 (DES DR 1) which is two order of magnitude shallower than the data from HSC. The transformer ensemble model achieved a classification accuracy of 95% on the data from DES DR1 and achieved a recall rate of 92% on the HSC dataset. Using the transformer ensemble models we identify a sample of 176 LSBGs among which 90 are completely new from the cluster Abell 194. We further classify 22 LSBGs among them as ultra-diffuse galaxies (UDGs). We show that transfer learning from a shallow survey to a deeper survey using transformer models can be successful with appropriate data normalization. This methodology could prove valuable for identifying and analyzing astronomical data in upcoming surveys like LSST and Euclid

The latest from Galaxy Zoo

Prof Karen Masters[1], Sandor Kruk[2]

[1]Haverford College. [2]ESA

Abstract

The Galaxy Zoo project (www.galaxyzoo.org) has over the last sixteen years of operation, provided quantitative visual morphologies for millions of galaxies, including samples such as the entire Sloan Digital Sky Survey Main Galaxy Sample (Lintott et al. 2011, Willett et al. 2013), all public Hubble Space Telescope surveys (Willett et al 2016; Simmons et al. 2017), more recently 8.7 million galaxies in DECaLS (Walmsley et al. 2023). The morphological information collected by Galaxy Zoo has shown itself to be a powerful database for studying galaxy evolution, with hundreds of papers making use of the data as an important characteristic to understand in the physics of how galaxies assemble, and how they regulate their star formation.

In this presentation I will give an update on the latest scientific results and analysis related to the Galaxy Zoo project, which might include information about results from the latest JWST images on the site; ongoing work to include machine learning in the loop with citizen scientists for optimal results (e.g. Walmsley et al. 2022, 2023); some of the latest science results (e.g. Geron et al. 2023) or results from spin off projects like Galaxy Zoo: 3D (Masters et al. 2019) which provided feature masks for the MaNGA sample, or Galaxy Zoo: Clump Scout (Dickinson et al. 2022).

Searching for merging galaxy clusters: developing a method to identify clusters with substructures

Giulya Souza, Eduardo Cypriano, Lia Doubrawa

IAG - USP

Abstract

Galaxy cluster mergers release enormous amounts of gravitational energy, second only to the Big Bang itself. Studying such systems illuminates the dynamics and interactions of their main components: the intra-cluster gas, dark matter and galaxies. This work aims to identify and characterize these merging systems using optical data from the S-PLUS survey.

In this study, we apply the Adaptive Membership Estimator (AME) to a cluster catalogue. AME incorporates the full photo-z PDFs and a hierarchical density-based spatial clustering algorithm to assign membership probabilities to galaxies. This approach also enables the detection of sub-structures within clusters, indicating potential merging cluster candidates.

Due to the low number of galaxies in most individual systems collected by our method, a stacking technique was employed. As a result, we found that the galaxy density map of the stacked clusters reveals a bimodal distribution of galaxies, showing a clear sign of sub-structure.

To test the accuracy of AME in identifying sub-structures, we conduct controlled simulations of galaxy clusters, comparing the performance of AME with the MClust method, which assumes a Gaussian model for group and subgroup identification. For the next steps, we will complete our analysis using weak gravitational lensing techniques to perform mass maps of the identified systems. To confirm whether the clusters with sub-structures detected by AME are good candidates for fusion systems, we expect the mass distribution of these systems to be equally bimodal, as is the distribution of galaxies.

Structure and Kinematics of Star-forming Elliptical Galaxies in SDSS-MaNGA

PRALAY BISWAS, YOGESH WADADEKAR

National Centre for Radio Astrophysics

Abstract

We examined the properties and formation modes of star-forming elliptical (SF-E) galaxies by utilising spatially resolved spectroscopy from the SDSS-MaNGA. To do this, we combined the GSWLC-A2, MaNGA Deep Learning Morphology, and MaNGA Pipe3D catalogues. We identified a rare population of 59 SF-Es, which we used as our primary sample. We also created two control samples of star-forming spirals (SF-Sps) and quenched ellipticals (Q-Es) to compare with our primary sample. We found that the Hα emission line flux of SF-Es is similar to SF-Sps, and the D4000 spectral index of SF-Es ranges from 1.2 to 1.8, indicating a mixture of old and young stellar populations. The mass-weighted stellar age and metallicity for the SF-Es are lower than the Q-Es. Additionally, 67% of the stellar and gas velocity maps of the primary sample show signs of kinematic disturbance. These findings suggest that SF-Es have acquired metal-poor gas in recent mergers or interactions with other galaxies and are forming a new generation of stars. Furthermore, we subdivided our primary sample of SF-Es into four classes based on their B/T and λ_{re} values. The properties of the galaxies in these four classes show that they all have their own distinct evolutionary history and modes of formation. Based on these results, we conclude that the Hubble diagram does not accurately capture the galaxy evolution processes. Instead, we need a revised morphology diagram like the comb morphology diagram to better understand galaxy evolution processes.

The low/moderate star formation at *z*~0, early stellar growth and the 'Missing Baryons' in massive and fast roating disc galaxies

Shankar Ray[1], Suraj Dhiwar[2], Joydeep Bagchi[1], M. B. Pandge[3]

[1]CHRIST (Deemed to be University), India. [2]IUCAA, India. [3]Dayanand Science College, India

Abstract

We investigate five fast-rotating and massive galaxies with rotational velocities of more than 300 km/s. Based on the ultraviolet data from UVIT, these galaxies show low to moderate recent star formation rates of ~1.4-13.7 solar masses/yr, and fall below the star formation main-sequence relation at *z*~0, with specific star formation rates $<10^{-10.5}$ yr^{-1}. We identify localized star-forming clumps with mean star-forming densities of 0.011-0.098 solar masses/yr/kpc^2 from the far-ultraviolet imaging, indicating concentrated young star-forming activity of ~ 100 Myr. The objects with recent high star formation show structural asymmetries, potentially influencing their star-forming activity. However, their star formation efficiency remains low (~7-31 percent) in converting the dark-matter halo baryons into stars in the galactic disc. The far-ultraviolet to far-infrared spectral energy distribution modeling shows that the peak star formation of the objects happened at a time before/leading up to the cosmic high noon/quasar epoch (redshift ~1-3), with 31-42 percent of the stellar mass of the objects forming within 1/16 to 1/5th of the age of the Universe. We find these galaxies deviate from the Baryonic Tully-Fisher relation, with their baryonic mass $>10^{11}$ solar masses. The galaxies lack ~67-92 percent of baryons in their dark-matter halos ($>10^{13}$ solar masses) as per the cosmological baryon fraction of ~0.17, termed the "Missing Baryons". The detected hot gas (~10^6 K) in the halos of some of the galaxies is of ~10^{10} solar mass, far less than the expected mass of ~10^{12} solar mass.

Probing the formation histories of NSCs in the Fornax Galaxy Cluster using UVIT

Dr. Prasanta Kumar Nayak[1], Prof. Thomas H. Puzia[1], Dr. Paul Eigenthaler[1], Dr. Yasna Ordenes-Briceño[1], Dr. Mareclo Mora[2], Dr. Bryan Miller[3], Dr. Matías Blaña[1], Dr. Evelyn Johnston[4], Dr. Tuila Ziliotto[5], Rohan Rahatgaonkar[1]

[1]Pontificia Universidad Católica de Chile.. [2]Las Campanas Observatory. [3]Gemini Obseratory/NSF's NOIRLab.. [4]Universidad Diego Portales.. [5]Università degli studi di Padova.

Abstract

The correlations between nuclear star clusters (NSCs) and their host galaxy indicate a fundamental connection between the formation of NSCs and their parent galaxy. A recent study by the Next Generation Fornax Survey (NGFS; Ordenes-Briceño et al. 2018) shows the presence of relatively massive nuclei in the faint dwarf at lower galaxy mass regime $\log(M_{gal}/M_{Sun}) < 9.5$, which could be due to recent or ongoing star formation activity that contributes to an earlier build-up of nuclei relative to the rest of the galaxy. The NUV-optical-NIR colour-colour diagram also indicates the presence of young stellar populations (less than 2 Gyr). Extending the SED coverage beyond the Balmer break to FUV allows us to determine the age and mass fraction of these young stellar components more accurately by combining data from NGFS. So, we obtained FUV data of two massive NSCs from Ultra-Violet Imaging Telescope (UVIT) onboard AstroSat through a successful proposal in the current observing cycle. I will present preliminary results from this current observation.

Abstract

The presence of Active Galactic Nuclei (AGN) can affect the morphological parameters and classification of active galaxies and have subsequent consequences when studying galaxy evolution. We study how the AGN contribution may affect the most commonly used morphological parameters at redshift z~0 and up to redshift z∼2. We use a sample of over 2000 non-active local galaxies, with well-known visual morphological classification, and add an AGN as an unresolved component contributing 5%, 10%, 25%, 50%, and 75% to the total galaxy flux. We then analyse the impact of the added AGN contribution to commonly used morphological parameters, including various concentration, asymmetry and smoothness indices when dealing with early- and late-type galaxies at z ~ 0, finding a significant change in the parameters, above 20%, when the AGN contribution to the total flux is higher than 25%. We then moved all local galaxies to fainter magnitudes (higher redshifts) to map the conditions in the COSMOS field. Finally, we study the effect of 5-75% AGN contributions on the four parameters taking into account the effect of magnitude (from 21 to 25 in the g-band) and redshift (up to z∼2). In general, the four morphological parameters will change > 20% if the AGN contribution is >25%, and for mag > 23 in g-band, with spirals being more affected than early-type galaxies. If the AGN contribution to the total galaxy flux is ≥ 50% (lower at magnitudes <23), the AGN effect will play a key role in the behaviour of the morphological parameters.

Detailed star formation histories from deep spectroscopic studies of galaxies

Dr. Thiago Goncalves

Valongo Observatory. Federal University of Rio de Janeiro

Abstract

Galaxies show a clear dichotomy in their properties between blue spirals and red ellipticals. This means galaxies must undergo some physical transformation that prevent them from further forming new stars. In this talk I will discuss a series of results that aim to measure and understand star formation quenching. This includes the use of spectroscopic indices, in tandem with broadband colors, to infer parameters of the star formation history of galaxies, showing that galaxies quench faster in the early universe, with possible connections with merging activity and more prevalent AGN feedback at high redshifts. Later, we have investigated the possible correlation between quenching timescales and other processes, in an attempt to further understand the main drivers of galaxy evolution and transformation between the two populations. This has been made possible by a recent measurement of the instantaneous derivative of the star formation rate of a galaxy — a quantity we have called “star formation acceleration”, or SFA. This strongly depends on AGN activity and galaxy environment, as would be expected from galaxy evolution models. It has also been shown that ellipticals show higher SFA values, i.e., they quench faster than spiral galaxies with similar colors, presenting strong evidence that morphological transformations are tightly correlated with distinct star formation histories. Finally, I will show how these studies will be impacted by the upcoming generation of ground-based telescopes, with the multi-object spectrograph MOSAIC, to be installed at the ELT, allowing for the same diagnostics to be extended to fainter, more distant galaxies.

The impact of different models on spectral fitting of young stellar populations in spiral galaxies

Geraldo Gonçalves[1], Luiz Silva-Lima[2], Paula Coelho[1], Lucimara Martins[2]

[1]Instituto de Astronomia, Geofísica e Ciências Atmosféricas, Universidade de São Paulo.
[2]Universidade Cruzeiro do Sul

Abstract

The pixel-to-pixel spectral fitting technique is often used in studies of stellar populations. It enables the user to infer several parameters from integrated light spectra such as ages and chemical abundances of galaxies and star clusters. In this work, we have used this technique to study the young stellar populations present in the central regions of some spiral galaxies. These objects can present inner structures, such as inner disks and rings, that can be formed by gas brought from the main disk to the center of the galaxy. We have used IFU data from the TIMER survey (Gadotti+19) of 11 galaxies and models from four different libraries: MILES (Vazdekis+15), Starburst99 (Leitherer+99), HR-pyPopstar (Millán-Irigoyen+21) and XSL (Verro+22). The results show that age values from spectral fitting are consistent with different models, but metallicity values can show significant differences. In some cases (NGC1097, for example), different structures can be seen in [M/H] maps inferred with different model libraries. With this work, we expect to shed light on the importante of the choice of a model library when retrieving information via spectral fitting, mostly (but not only) in objects with a high density of young stellar populations.

miniJ-PAS: the physical nature of galaxy morphologies

Arianna Cortesi[1,2], Fabricio Ferrari[3]

[1]Institute of Physics - Federal University of Rio de Janeiro - Brazil. [2]Observatory of Valongo - Federal University of Rio de Janeiro - Brazil. [3]Universidade Federal do Rio Grande, Instituto de Matematica, Estatistica e Fisica, Rio Grande, RS, Brazil

Abstract

To investigate the physical nature of galaxy morphology and its evolution through cosmic times, we use miniJ-PAS data to characterise their morphometric properties as derived with MFMTK, and we combine the results with existing VAC catalogues from miniJPAS data service, specifically stellar population properties, environment and photometric redshift. In this work, we present a catalogue of morphological parameters for 2000 galaxies in the AEGIS field, obtained for the miniJ-PAS g,r,i bands, comprising non-parametric (concentration, asymmetry..) and parametric (Sersic index, ..) estimations. We compare the recovered Sersic index and Effective radii with previous works based on HST data, for different magnitude bins, finding a good agreement for rmag<=21. We study the relation between galaxy stellar population, intrinsic colour, mass and the morphometric parameters (especially C1, M20, H), for different spatial resolution, redshift and magnitude bins. The clear correlations found, reflects the known relation between galaxy morphology, colour and stellar population. Moreover, the correlation between mass and morphometric parameters suggest a deep connection between such parameters and the galaxy potential. Finally, a more complex trend is found between morphometric parameters and the galaxy environment. M20, A, H, and the Gini parameters are most sensitive to environmental effects as they relate to perturbations in the isophotal profile, possibly due to interactions in high-density regions.

[6]INAF - Osservatorio Astronomico di Brera, Via Brera 28, 20122 Milano, via E. Bianchi 46, 23807 Merate, Italy

Abstract

Because quiescent galaxies were more compact at higher redshift compared to what is observed in the local Universe, it is believed that the average size increases through different mechanisms (AGN feedback, mergers, etc.). Nonetheless, this observed size evolution is still debated nowadays, as it may also be explained, at least partially, by quenched star-forming galaxies entering the quiescent population.

Using the VIMOS Public Extragalactic Redshift Survey, we look at the mass-size relation of the quiescent galaxies, to understand how this population evolved from z=0.9 to z=0.5. The sample of passive galaxies is selected from the NUVrK diagram and a constraint on D4000, a tracer of galaxy's age. We study the mass-size relation and the effect of environment through the density contrast to understand the mechanisms that would be responsible for the apparent size evolution. We show that the average size of quiescent galaxies is similar in low and high density environment and that minor mergers alone cannot explained the observed size evolution from z=0.9 to z=0.5.

A Viable Non-Canonical Scalar Field Model to Inflation

MSc Pedro Almeida, Prof. Dr. José Ademir Lima

IAG - University of São Paulo

Abstract

A new deflationary cosmology driven by a non-canonical scalar field is proposed. The model describes analytically a smooth dynamic evolution from an initial and structurally unstable de Sitter inflationary stage to the standard radiation phase. The selected potential V(Φ) can also be interpreted as a running vacuum cosmology whose evolution is driven by a specific Λ(H)-term, where H is the Hubble parameter. At the end of the decaying vacuum process, the remaining energy density is completely stored in the kinetic part of the field which satisfies the radiation equation of state. The very early Universe is non-singular, free of horizon and unlike many inflationary variants, none super-cooling and post-inflationary reheating process is required. The thermodynamic evolution of the thermal bath is determined and the general conditions for a slow-roll deflation are discussed. The Planck data for the spectral index and tensor-to-scalar ratio are used to constrain the free parameters of the model.

Calibrating the color-redshift relation for an optimum exploitation of Euclid data

Dr. Carlos Gutierrez

Instituto de Astrofísica de Canarias. University of La Laguna

Abstract

Euclid's three dimensional reconstruction of the matter distribution in the Universe heavily relies on a proper calibration of the color-redshift relation. Getting such calibration was the motivation of the project Complete Calibration of the Color-Redshift Relation (C3R2) survey (Masters et al. 2017), with the goal of mapping the empirical relation between galaxy redshift and colors to the Euclid depth of i∼24.5(AB). The survey strategy is based on the fact that the diversity in observed galaxy colors at a given survey depth is limited and on the assumption that there exists a well-defined, mostly non-degenerate relation between a galaxy's position in multi-color space and its redshift, which can be traced empirically. The programme involved the spectroscopic observation of a few thousand of galaxies using the telescopes Keck, VLT and GTC. Here, we present the status, results and plans to complete the participation of our group in such project.

The contamination of primordial non-Gaussianity from relativistic Doppler and wide-angle effects.

Dr SECLOKA LAZARE GUEDEZOUNME, Dr SHEEAN JOLICOEUR, Prof ROY MAARTEENS

Department of Physics & Astronomy, University of the Western Cape, Cape Town 7535, South Africa

Abstract

The distortions in the galaxy number count introduced by perturbations in the spacetime can be measured by the Fourier power spectrum and bispectrum. The study of these spectra often makes use of the distant observer approximation where the line-of-sight (LOS) vectors are always parallel. But, it has been shown that going beyond this plane-parallel assumption introduces wide-angle corrections to the power spectrum and bispectrum. For the bisector LOS definition, the wide-angle effects are non-negligible and can lead to potential contamination of local fNL measurements. In this work, we generalize the results, both in the single and multi-tracer cases, for all possible LOS definitions that can be parameterized by a free parameter in the power spectrum. We focus on low redshifts where the wide-angle effects are larger and therefore, we can safely neglect the lensing contribution. We consider the non-integrated redshift-space distortions and relativistic Doppler terms in our perturbative expansion of the wide-angle corrections and include the primordial non-Gaussianity through the bias tracers.

Exploring southern galaxy groups and clusters with S-PLUS/DR4

Lia Doubrawa, Eduardo Cypriano

Instituto de Astronomia, Geofísica e Ciências Atmosféricas da Universidade de São Paulo (IAG/USP)

Abstract

This study relies on the galaxy cluster and group detection and characterization utilizing the latest data release of the Southern Photometric Local Universe Survey (S-PLUS/DR4), covering approximately 3000 square degrees. We use the cluster finder algorithm PZWav, within the redshift range of $0.05 < z < 0.5$, to identify galaxy group and cluster candidates due to its feature to handle the probability density function of the redshift. This ability is essential in recent imaging surveys that utilize narrow-band filters, such as S-PLUS, as it allows the exploration of precise photometric redshift estimates. With a similar approach, previous studies with miniJPAS show that we recover structures with $4{\cdot}10^{13}$ solar masses at redshift 0.75. We expect to achieve a similar sensibility with S-PLUS. Additionally, we offer insights into the candidates' galaxy members by applying our adaptive membership estimator algorithm. With the membership probabilities, we estimate richness and optical luminosity for each cluster. Finally, we validate the quality and completeness of the algorithms through comparisons with the literature and tailored simulations. We find that our catalog achieves 80% purity and 95% completeness for structures with a richness greater than 4, corresponding to clusters with masses exceeding 10^{14} solar masses. The comparisons with Sunyaev–Zel'dovich-based detections in STRIPE82 demonstrate an 87% recovery rate, with center variations of $\Delta R = 187 \pm 96$ kpc and $\Delta z = -0.004 \pm 0.013$ in redshift. This investigation emphasizes the potential of the S-PLUS survey and the applied methodologies.

Probing the Association of Galaxy Clusters with Bent-Tailed Radio Sources Using the MeerKAT Galaxy Cluster Legacy Survey

Mr Toivo Samuel Mabote

University of Pretoria

Abstract

In this presentation, I will delve into my extensive research on Bent-tailed radio galaxies (BT) derived from the MeerKAT Galaxy Cluster Legacy Survey. Leveraging publicly accessible imagery, I have meticulously compiled the most comprehensive catalogue of BT galaxies to date. My discussion will center on elucidating the intricate sample selection process and uncovering the significant insights yielded by this catalogue regarding the physical attributes and connections between BT galaxies and their respective host clusters. Through this exploration, I aim to shed light on the dynamic interplay shaping galactic environments, offering valuable contributions to our understanding of cosmic evolution.

The Stellar Mass Distribution of the Galactic Center's Nuclear Star Cluster

Brian Murphy

Butler University

Abstract

The direct Fokker-Planck method is employed to develop a dynamically evolving model of the stellar distribution of the nuclear cluster surrounding the massive black hole (MBH) at the Galactic Center. This model incorporates a range of stellar masses from 0.1 to 50 solar masses. Initially, the model features a seed black hole, which undergoes growth through various mechanisms such as tidal disruption and stripping of stars, stellar collisions, and mass loss due to normal stellar evolution. After 13 billion years, the most suitable model has the MBH and the surrounding nuclear cluster with masses of 4.3 and 23 million solar masses, respectively, with the nuclear cluster having a half-mass radius of 5.7 parsecs.

This model accurately reproduces the K-band surface luminosity profile to radii of less than 0.1 arcsecond and provides a natural explanation for the absence of giant stars observed by others at these radii. These giant stars not only experience collisions but can also undergo tidal stripping of their outer layers during their evolution. Although stellar mass black holes constitute only 2.5% of the total mass of the nuclear cluster, they significantly influence the stellar distribution within the inner 0.25 parsecs. The population of stellar black holes has a half-mass radius of 1.96 parsecs. Within distances of 0.01 and 0.1 parsecs from the center, the model predicts the presence of 130 and 1950 stellar mass black holes, respectively, aligning well with observational limits derived from the orbits of S stars.

Electron Temperature, Metallicity, and the Ionizing Source of Local Analogs of High-z Galaxies

Dr. Valentino Gonzalez, Benjamin Navarrete

Universidad de Chile

Abstract

Strong nebular emission lines in the optical are routinely used to study the ISM of galaxies. In fact, thanks to the JWST, such measurements are now possible for galaxies at very high redshifts (z>7), well into the epoch of reionization (EoR). Often, the physical properties derived from these lines rely on local calibrations that are not necessarily accurate for the extreme populations that the JWST has been uncovering in the distant Universe. In this work, we present a sample of local galaxies with strong-line ratios (e.g., OIII/Hb, NII/Ha) similar to those of z≥3 galaxies for which we have acquired very deep optical and NIR spectra. The data reveal weak lines (e.g., [OIII]4364, [OII]7319+7330 [SIII]6312, [NII]5755) that are difficult to observe directly on distant galaxies, even with the JWST, and that allow us to make multiple estimates of the electron Temperature and density, as well as metallicities for these local analogs of high-z galaxies. Furthermore, our NIR spectra allow us to constrain the dominant ionizing source, distinguishing between massive stars, AGNs, and shocks. This is based on BPT-like diagnostics but using NIR lines such as FeII 1.64, H2(1-0)S(1), and Brγ. Similar NIR measurements directly on EoR galaxies are beyond the wavelength reach of the JWST (because of the large redshifts), so this could be our best clue about what is, most likely, the dominant source ionizing the ISM of the most distant galaxies.

Cosmic magnification in beyond-Horndeski gravity

Dr Didam Duniya[1], Dr Bishop Mongwane[2]

[1]Botswana International University of Science and Technology. [2]University of Cape Town

Abstract

The cosmic magnification is able to probe the geometry of large scale structure on cosmological scales, thereby providing another window for probing theories of the late-time accelerated expansion of the Universe. It holds the potential to reveal new information on the nature of dark energy and modified gravity. By using the angular power spectrum, we investigated cosmic magnification in beyond-Horndeski gravity. We incorporated the known relativistic corrections and considered only large scales, where relativistic effects are known to become substantial. We probed both the total relativistic signal, and the individual relativistic signals. Our results suggest that surveys at low redshifts ($z \lesssim 0.5$) will be able to measure directly the total relativistic signal in the total magnification angular power spectrum, without the need for multi-tracer analysis (to beat down cosmic variance); similarly, for the Doppler signal, at the given z. However, for the integrated-Sachs- Wolfe, the time-delay, and the (gravitational) potential signals, respectively, it will require surveys at high redshifts ($z \gtrsim 3$). For both aforementioned sets of signals, their amplitudes at the given z will ordinarily surpass cosmic variance, and hence, are able to be detected directly; whereas at other z, multi-tracer techniques will need to be taken into account. We also found that the beyond-Horndeski gravity boosts relativistic effects; consequently, the cosmic magnification. Conversely, relativistic effects enhance the potential of the total magnification angular power spectrum to detect the imprint of beyond-Horndeski gravity.

Constraining Late-Time Physics to Solve the Hubble Tension

Sebastián Rueda-Blanco[1], Dr. Camilo Delgado-Correal[2,3], Dr. Mario-A. Higuera-G.[1], Dr. Sergio Torres Arzayus[4]

[1]Universidad Nacional de Colombia, Observatorio Astronómico Nacional - OAN. [2]Francisco José de Caldas District University of Bogotá. [3]Geographic Institute Agustín Codazzi - IGAC. [4]International Center for Relativistic Astrophysics Network, Piazza della Repubblica 10, 1-65122, Pescara, Italy

Abstract

In this work, we analyze Type Ia supernovae (SNe) data to constrain the equation of state (EOS) of dark energy (DE), defined as $\omega = P/\rho$, within the context of the Hubble tension. Previous studies on dynamic DE models suggest that while DE alone cannot completely resolve the tension, it remains a viable candidate and may contribute to its alleviation. To guide theoretical developments concerning the EOS, we propose a physics-agnostic approach to constrain DE using both supernovae and CMB data. Our approach involves fixing pre-recombination physics, firmly established based on CMB observations, and examination of SNe data for late-time effects hat could alleviate the tension. In order to achieve this, we introduce a simple parametrization of the EOS, employing a sigmoid function that explicitly encodes a transition redshift where ω transitions from -1 (consistent with CMB observations) to its present value, ω_0. This parametrization enables DE to influence late-time expansion without disturbing early CMB physics. The primary dataset utilized in our analysis comprises Type Ia supernovae sourced from the Pantheon+ compilation, with a focus on selecting SNe within the Hubble flow sector ($z > 0.15$), where late-time physics effects would take place. Driven by the approach of fixing pre-recombination physics, we incorporate cosmological probes (CMB) not by merging the data, but rather as constraints. We present fits of cosmological parameters to the data, conduct analysis of parameter degeneracy, and incorporation of CMB constraints. The collective findings serve as a valuable resource for formulating theoretical models pertaining to the EOS.

N-body simulations of the formation of halo substructures in spiral galaxies in merger events

Dr Stanislav Milošević

University of Belgrade, Faculty of Mathematics

Abstract

We investigate galactic dynamics and the evolution of halo structures in spiral galaxies using N-body simulations. These structures are formed through mergers between large spiral galaxies which we refer to as a host with its satellite dwarf galaxy. We tested different morphology and orbit orientation of the dwarf to describe different properties of the formed structures in the halo of the host. Particulary we took M31 as a host galaxy and probed different merger scenarios to explain the formation of the Giant Stellar Stream (GSS) and Northeast (NE) and West (W) shelves observed in the halo of M31. With dwarf spheroidal galaxy (dSph) we reproduced observed values of distances and velocities along the Stream. Using Monte Carlo simulations (MC) and with linearly decreasing function for the initial metallicity distribution in a dwarf galaxy, we explained the observed metallicity distribution along and across the Stream. We traced particles from the dwarf galaxy in the simulations of the merger event. As they carry their metallicities, we calculate the final metallicities in observed fields and match them with the observed ones. With linearly decreasing gradient we explained metallicity in the GSS as well as in the NE and W shelves.

Photometric Synthesis with AI of S-PLUS galaxies

Mr Vitor Cernic

Universidade de São Paulo

Abstract

This study explores a new method for estimating stellar population parameters from galaxy parameters with the aid of Deep Learning techniques. By analyzing data from the S-PLUS photometric survey, we compared different regression models, including Random Forest, XGboost, and Neural Networks, to identify the most suitable estimator. To address challenges like missing data and calibrations, we developed a robust synthetic training sample that closely resembled real observations. The Neural Network model exhibited promising results, with a low error of 0.06 dex for stellar mass estimation [attached image] and accurate predictions of nine other stellar population parameters. The approach allows for constraints-free, fast parameter estimation compared to traditional methods constrained by redshift. As a testament to the effectiveness of our approach, we present new data analysis of nearby galaxy clusters, such as Fornax and Abell 85, showcasing the potential of our method in studying diverse galactic populations. We also apply this method to the S-PLUS and CHANCES surveys, with a focus on obtaining previously unseen galaxy parameters and intend to make this data public. This novel approach has the potential to significantly advance our understanding of stellar populations and contribute to the progress of galaxy research.

Neighbourhood Watch: A Survey of Baryonic Substructures in the Nearby Universe

Rohan Rahatgaonkar[1], Bryan Miller[2], Thomas Puzia[1], Yasna Ordenes-Briceño[1], Paul Eigenthaler[1], Tuila Ziliotto[3], Mathew Taylor[4], Juan Pablo Carvajal[1]

[1]Pontificia Universidad Católica de Chile. [2]Observatorio Gemini Sur, NOIRLAB. [3]Università degli Studi di Padova. [4]University of Calgary

Abstract

The Neighbourhood Watch is a survey to complete a census of all baryonic structures out to at least the virial radius in a sample of galaxy groups within 18 Mpc in the optical filters u'g'r'i' and H-alpha with CTIO/DECam and in the NIR J,K filters with ESO/VIRCAM. The observations reach unprecedented point source depths of 2.5 magnitudes beyond the peak of the globular cluster luminosity function (GCLF) which will detect > 99% of all compact objects, i.e. globular clusters (GCs) and ultra-compact dwarf galaxies (UCDs), and reveal all low-surface brightness baryonic structures down to ∼28mags/arcsec2.This dataset will allow us for the first time: to derive a complete GCLF out to the virial radius for these galaxies, search for spatial over-densities and unique age/metallicity distribution functions in the GC population, detect 10-100 new low-surface brightness dwarf galaxies for each target group to test current state-of-the-art cosmological simulations and measure their luminosity function in different environments, and probe the complex interaction/merger/accretion history of these groups. Given the DECam community pipeline's inability to properly determine the sky levels around large galaxies, a custom data reduction pipeline has been designed for this particular dataset that employs a combination of different image processing techniques (convolution masking, distortion reduction in chip gaps, adaptive sky modal) leading to improved retrieval of low-surface brightness dwarf galaxies in the final stacks. This talk will give an overview of the survey and present analysis of the final stacks in relation to the objectives mentioned above.

A New Era of Resolved Physics

A/Prof Aaron Robotham

UWA

Abstract

Here I will present recent work using our new “ProFuse” resolved spectral energy distribution software. Applying this to the 21 bands of UV-FIR data of the Galaxy And Mass Assembly (GAMA) survey we have discovered new insights into the resolved properties of 10,000 galaxies. Highlights include the existence of a fundamental size-mass-age plane for disks, and the truly relic nature of most classical bulges- being significantly older than even elliptical galaxies. This work is now moving into space, with deep highly resolved surveys taking place with JWST (Pearls) and Euclid (the WAVES legacy science survey).

Challenging the standard cosmological model using HII galaxies with the JWST

Dr. Ana Luisa González Morán

The Autonomous University of Sinaloa (UAS, México)

Abstract

The Standard Model of Cosmic Structure Formation (ΛCDM model) explains the history of the Universe as a succession of epochs characterized by their expansion rates. The cosmological parameters Ω_m, Ω_{Λ}, and w_0 (plus w_a in the evolutive case) are obtained by combining the low-redshift results (z $\lesssim$ 2) for baryon acoustic oscillations (BAOs) and type Ia supernovae (SNIa) with high-redshift results (z $\sim$ 1000) given by Planck CMB fluctuations. It is important to remark that there are no determinations of cosmological parameters at intermediate redshift (2 $\lesssim$ z $\lesssim$ 8), where the maximum difference in cosmological models that include an evolving Dark Energy Equation of State (DE EoS) occurs. Here we present independent determinations of cosmological parameters using the distance estimator based on the established correlation between the Balmer line luminosity, L(Hβ), and the velocity dispersion (σ) for H II galaxies (HIIG) up to z~ 8. These results are based on 229 HIIG where 6 were observed using the JWST at 5.5 $\lesssim$ z $\lesssim$ 7.5. The results showed in this work are in excellent agreement with the ΛCDM model obtained from similar analyses using Type Ia supernovae. We anticipate our assay to be a starting point to measure with high-precision the DE EoS and to explore its evolution (or lack of it) with look-back time as well as searching for hints of any other property of DE making use of more JWST high-z HIIG data.

WAVES: The Wide Area VISTA Extragalactic Survey

Sabine Bellstedt

ICRAR-UWA

Abstract

The WAVES survey is a major galaxy redshift survey that will be conducted on 4MOST, scheduled to begin its scientific operations in 2025. Expected to collect redshifts for 1.6 million galaxies, this survey will build a highly complete view of galaxy environment, over large areas of the sky, and also extending out to z=0.8. The backbone of this project is the wealth of multi-wavelength imaging data, which has been meticulously processed to produce an enormous photometric catalogue over ~1300 square degrees. This input catalogue will facilitate one of the first survey selections with a photometric redshift cut - a critical element of WAVES. I will present the WAVES sub-surveys, targeting strategy, and an overview of the wealth of science expected to be conducted with the data in the coming years.

Probing the low-frequency radio luminosity - star-formation rate relation for star-forming galaxies with LOFAR

Dr Ikechukwu Obi[1], Prof Huub Röttgering[2], Dr Bonaventure Okere[1]

[1]Centre for Basic Space Science & Astronomy (CBSS). [2]Leiden Observatory, Leiden University, The Netherlands

Abstract

We investigate the relationship between the low frequency radio luminosity and key physical properties of nearby star-forming galaxies (SFGs) by exploiting LOFAR (Low Frequency Array, The Netherlands) 150 MHz observations of the ELAIS-N1 (European Large Area ISO Survey North 1) field. We model the UV-radio SEDs of a sample of SFGs in this field with the SED fitting code, Galapy-fit, which incorporates the most recent PARSEC SSPs. These SSPs are unique when compared to those used in other fitting codes in that the non-thermal (synchrotron) radio emission which dominates at low frequency, are not computed from the far-infrared-radio correlation but from core-collapse supernova (CCSN) rates and accounts for recent advances in CCSN explosion models. We present the results of our multi-wavelength analysis which aims to shed more light on the usage of low frequency radio luminosity as a SF tracer. We compare our results with those of other works in the literature, both at 150 MHz and at 1.4 GHz.

Measuring the Hubble Constant with Mira Variables

Dr. Caroline Huang

Harvard-Smithsonian Center for Astrophysics

Abstract

Precise, cosmic distance ladder measurements made with Cepheids have revealed a 5σ discrepancy in the observed rate of expansion of the universe at the present day (the Hubble Constant) and the rate predicted by observations of the Cosmic Microwave Background assuming a standard Lambda-Cold Dark Matter cosmology. With no obvious solutions to the tension, this discrepancy has been one of the strongest indications of physics beyond the Standard Model of Cosmology. As a result, the use of multiple, independent methods measuring the Hubble Constant is integral to resolving or solidifying the tension. Mira variables – highly-evolved asymptotic giant branch stars – have gained attention as an alternative precision distance indicator and calibrator of Type Ia supernovae to the more widely-used Cepheid or Tip of the Red Giant Branch stars. In addition to being highly luminous and ubiquitous, they are capable of being easily detected and characterized using only near-infrared and infrared observations, which is particularly advantageous in the era of JWST and Roman. In my talk, I will discuss current progress in the development of the Mira distance ladder and its Hubble Constant measurements. In particular, I will focus on recent HST and JWST observations of Mira variables in M101, the nearest recent host galaxy of a Type Ia supernova.

Unveiling the Warm Molecular Hydrogen Reservoir in the Circumgalactic Medium of MACS1931-26's Brightest Cluster Galaxy: Insights from JWST/MIRI Observations

Lucas Kuhn, Dr. Allison Man

The University of British Columbia

Abstract

We present JWST MIRI observations of the warm molecular hydrogen in the circumgalactic medium (CGM) of the brightest cluster galaxy (BCG) of MACS1931-26. This target harbors one of the largest known H2 reservoirs in a cluster core revealed by ALMA. Its cold gas, as traced by CO, is spatially extended over a tail of ~30kpc beyond the BCG core. Submillimeter observations reveal extreme thermal and excitation conditions in the CGM gas: the dust and gas are thermally decoupled, and the CGM is unusually highly excited pointing to a drastically different condition in the CGM than typical gas found in galaxies. We utilize MIRI/MRS to map the 3D structure of the warm molecular gas in the BCG core and the extended CGM tail of MACS1931, and present the first detections of the spatial extent and temperature distribution of the warm H2 emission. Specifically, we create line maps using our detections of the H2 0-0 S(1) and S(5) lines which enables the measurement of the total gas mass and temperature distribution. We follow this by comparing the warm H2 emission to the cold H2 emission mapped by CO. In addition, we see evidence of shock-induced star formation with the presence of Polycyclic Aromatic Hydrocarbon (PAH) features in our spectra. By probing the CGM gas across a range of temperatures, we provide insight into the impact of AGN feedback on the baryon cycle, and assess the role of shocks and turbulence in the heating and cooling of the CGM.

A panchromatic view of the circumgalactic medium surrounding a brightest cluster galaxy at z=0.4

Prof. Allison Man, Lucas Kuhn, Laya Ghodsi

The University of British Columbia

Abstract

Star formation within galaxies is regulated by the circumgalactic medium (CGM) through gas inflows and outflows. I will present an analysis of the comprehensive view towards the multiphase (warm and cold molecular + ionized) gas and dust analysis of a BCG at z=0.4. The target harbours one of the largest known H2 reservoirs, elevated star formation, and a strong radio AGN. We obtained new JWST/MIRI MRS observations that detect warm H2 lines, indicating that the molecular CGM is warmer than the interstellar medium within the BCG. I will present preliminary results a joint analysis of the warm and cold molecular gas in the CGM and BCG, using ALMA and single-dish observations of CO and [CI] emission lines. Archival HST and VLT/MUSE observations enable us to tie the gas and dust conditions to the resolved stellar populations. I will discuss the implications of this work on the possible link between the enhanced star formation in this BCG and its CGM, as well as the role of AGN feedback in regulating star formation. This case study serves as a pathfinder for using JWST to complement existing multi-wavelength observations of the gas, dust and stars of massive galaxies and their CGM using JWST.

Abstract

Ultra-diffuse galaxies (UDGs) are attractive candidates to probe cosmological models and test theories of galaxy formation at low masses; however, they are difficult to detect because of their low surface brightness. In the Local Group a handful of confirmed and candidate UDGs have been found to date, most of which are satellites of the Milky Way and M31, and only three are isolated galaxies. It is unclear whether so few UDGs are expected. We address this by studying the population of UDGs formed in hydrodynamic constrained simulations of the Local Group from the HESTIA suite. For a Local Group with a total enclosed mass, M (< 2.5 Mpc) = 8×10^{12} $M_\odot$, we predict that there are 12 ± 3 isolated UDGs (68% confidence) with stellar masses between 10^6 and 10^9 $M_\odot$, and effective radii $R_e \geq 1.5$ kpc, within 2.5 Mpc of the Local Group, of which 2^{+2}_{-1} (68% confidence) are detectable and classified as UDGs in the footprint of the Sloan Digital Sky Survey (SDSS). Accounting for survey incompleteness, we find that almost the entire population of UDGs in the Local Group field would be observable in a future all-sky survey with a depth similar to the SDSS, the Dark Energy Survey, or the Legacy Survey of Space and Time. Our results suggest that there is a population of UDGs in the Local Group awaiting discovery.

[8]Technical University of Munich, School of Engineering and Design, Department of Aerospace and Geodesy, Germany

Abstract

Globular clusters are sensitive tracers of galaxy assembly histories. We examine how the mass ratio of major mergers affects the formation and disruption of globular clusters in a simulated present-day L^* galaxy. Starting from a zoom-in simulation of a system that experienced major mergers at z=1.7 and z = 0.77, we employ the genetic modification technique to enhance the mass ratio of the latter merger by a factor of two (enhanced case) or prevent it from occurring (suppressed case). The formation and evolution of star clusters is implemented using the MOSAICS model in the subgrid of the EAGLE hydrodynamics scheme. Our simulations reveal that most of the globular cluster system forms during the first merger and that most of the subsequent evolution is affected mainly by the characteristics of this merger. Late-time mergers, if they take place, play a minor role by prolonging the galaxy's phase of net star cluster formation by up to 1 Gyr after the coalescence of the remnant. At z=0 this manifests as an overabundance of massive star clusters in the enhanced case compared with the unmodified assembly history, while the suppressed case has more low-mass clusters. Two commonly used observational metrics to characterize the richness of globular cluster systems are the specific frequency and the specific mass. At z=0 we find that the latter is stratified as a function of the mass ratio of the target merger; however, the specific frequency is not. This feature could prove useful to elucidate the assembly histories of galaxies from present-day observations.

[4]National Astronomical Observatory of Japan. [5]The Graduate University for Advanced Studies (SOKENDAI). [6]Kagoshima University, Amanogawa Galaxy Astronomy Research Center

Abstract

Bar structures, prevalent in nearby galaxies, are thought to significantly influence galactic disk evolution since their formation. Archaeological studies of the Milky Way and nearby galaxies suggest their formations date back over 8 billion years, aligning with recent JWST and ALMA observations that have identified stellar bars and gaseous bars, respectively, at high redshifts (z=2-4). The bar structures revealed by ALMA are predominately found in dusty starburst systems with a star formation rate of 100-1000, which are presumably gas-dominated systems. In this talk, we present our analysis of the resolved dust and gas kinematics for the archetypal starbursting barred disk galaxy, BRI 1335-0417 at redshift z=4.4, yielding a detailed picture of such starbursting systems. Our findings include: (1) a gas bar offset toward the dust bar's leading edge, suggesting gas inflow along the bar; (2) disk kinematics displaying coherent, non-circular motion, with a rotation-subtracted velocity residuals revealing an m=2 spiral pattern that aligns with the spiral arm morphology in gas and dust, indicating disk vertical perturbations from gas accretion or satellite interactions; and (3) gas comprising 72% of the galaxy's total mass. These observations may indicate that significant gas flow maintains a high gas and baryon fraction high, making the disk unstable and conductive to bar structure formation even in the gas-dominated systems. This contrasts with well-studied models where stellar bars emerge from stellar disks. We will discuss bar formation in these systems, linking our observations with recent numerical simulations of high gas fraction disks that resemble this population.

Decoding SF Quenching in Massive Galaxies: A Multi-Parameter SDSS Analysis

Dr Duho Kim

Department of Astronomy and Space Science, Chungnam National University, South Korea

Abstract

The galaxy luminosity function reveals a sharper cutoff at the bright end than predicted by ΛCDM cosmology for dark matter halo masses. This points to baryonic processes – such as virial shock heating, AGN feedback, morphological quenching, and environmental effects – as key players in halting star formation. I investigate these mechanisms using Big Data clustering algorithms on SDSS catalogs. The immense data from the Rubin Observatory will amplify my analysis.

Secondarily lensed Einstein arc by the companion galaxy discovered in a galaxy lens

Dr Ming Zhang[1,2], Dr Qi Yuan[1,3], Mr Jin-Yin Liu[1,3], Dr Li Zhang[4]

[1]Xinjiang Astronomical Observatory, Chinese Academy of Sciences, 150 Science 1-Street, Urumqi 831001, China. [2]Key Laboratory for Radio Astronomy, Chinese Academy of Sciences, 2 West Beijing Road, Nanjing 210008, China. [3]University of Chinese Academy of Sciences, 19A Yuquan Road, Beijing 100049, China. [4]College of Big Data and Information Engineering, Guizhou University, Guiyang 550025, China

Abstract

In the previous HST image analysis, the looming diffuse emission close to the companion galaxy was speculated to be part of the galaxy's spiral arms, so its role in the lensing macromodel was not emphasized. In this study, researchers analyzed the tri-band images from optical to near-infrared captured by the WFPC2 and NICMOS cameras carried by the HST, and found that after subtracting the light model of the foreground galaxy and background quasars, in the residual image, the Einstein light arc is consistently visible, and its convergence center is just at the position of the companion galaxy. At the same time, researchers used the latest 8.4GHz global VLBI observations to successfully resolve the corresponding jet components in the secondary image. Together with the jet components in the primary image, those components constitute a dual-image-three-component constraint on the lens system, which gives the strongest point source location and flux constraints for this lens system. The researchers applied the optimized macromodel constrained by the VLBI point source to the HST tricolor images, further optimized the photometric model of the foreground lens galaxy and the background quasar, and obtained the consistent optimization of the lens model for both optical and radio observations. The model can perfectly produce the Einstein arc, which indicates it is from the extended structure of the background quasar host galaxy. It also shows that the power-law slope of the lens host galaxy is steeper than that of the isothermal ellipsoid model, and the weak curvature of the jet in the secondary image is also within the tolerance of the model.

Detecting Faint Radio Frequency Interference (RFI) in MeerKLASS Single Dish data

Tamera Kassie

SARAO/ University of Western Cape

Abstract

MeerKLASS is a single dish HI intensity mapping survey of the MeerKAT Telescope. Probing the 21 cm signal is coupled with challenges from foregrounds and radio frequency interferences (RFI) which contaminates the data, and in turn our cosmological signal. The MeerKLASS collaboration has produced a detection of the HI cosmological signal using cross-correlations with galaxy surveys. However, low-lying RFI still remains. By removing these low lying RFI we expect to have reduced data loss due to aggressive flagging of RFI contaminants across channels to increase our S/N for an improved detection of the 21 cm signal. Low lying RFI lies below the noise measurement of single dish instruments and would require an algorithm that is able to boost the sensitivity and contrast the underlying RFI for flagging. In this presentation I will highlight the SSINS (Sky-Subtracted Incoherent Noise Spectrum) Algorithm (Wilensky et al, 2019 PASP 131 114507) that I have adapted to be applied to the MeerKLASS data to remove faint RFI signatures.

A History of the Movement for Equity and Inclusion in Astronomy

Dr. Jörg Matthias Determann

Virginia Commonwealth University

Abstract

Astronomy is a field concerned with matters very distant from Earth. Most phenomena, whether observed or theorized, transcend human spaces and timescales by orders of magnitude. Yet, many scientists have been interested not just in the events that have occurred millennia before Earth's inception, but also in their very own society here and now.
Since the first half of the twentieth century, an increasing number of them have pursued parallel careers as both academics and activists. Besides publishing peer-reviewed papers, they have promoted a great variety of underrepresented groups within their discipline. Through conferences, newsletters and social media, they have sought to advance the interests of women, members of racial and ethnic minorities, LGBTQI+, and disabled people. While these activists have differed in the identities they focus on, they have come to share a conviction that equity and inclusion are crucial for scientific excellence as well as social justice.
This paper presents biographies and institutional contexts of key agents in the diversification of modern astronomy. The presentation argues that these individuals collectively formed a social movement that has sought to revolutionize science and make it far more just. As most are recent figures whose discoveries have not been commemorated by Nobel Prizes, they are relatively unknown among historians of science. Activist scientists have, however, been central to discussions about who has privileged access to the tools of astronomical inquiry, including powerful telescopes and extensive databases. As such, they have also significantly shaped views of our universe.

Learning the art of creating an environment that embraces diversity and fostersinclusivity, from celestial bodies.

Dr. Gemechu Muleta Kumssa

Space Science and Geospatial Institute (SSGI)

Abstract

Astronomy is a captivating field, attracting individuals from around the globe who possess a deep curiosity to understand the marvels of the universe. Through the pursuit of astronomical research, we can harness our understanding of the cosmos to tackle the challenges we encounter in our daily lives. The celestial bodies that populate our skies have the potential to impart invaluable lessons on the importance of embracing diversity and fostering inclusivity among all inhabitants of our planet. To achieve this, it is crucial to create an environment that nurtures imagination, respect, and empowerment for every individual, irrespective of their age or background. Within this framework, I have discussed how we can learn from the celestial systems to cultivate a genuine appreciation for diversity and inclusion.

Identifying Indigenous Astronomy Knowledge Systems in “westernised” indigenous communities

Dr Anton Binneman

NRF|SARAO. University of Johannesburg

Abstract

MeerKAT and the SKA-Mid Projects are changing the face of the central Karoo in the Northern Cape of South Africa. These projects are bringing opportunities to local communities that they would have never had if these projects did not happen. The projects provide opportunities in several different fields including Dark skies tours and Astronomy Tourism. To ensure that this is done sustainably the initiatives need to be unique to the area and the people who live there. The central Karoo is famous for the stories captured by Bleek and Loyd internationally and for numerous papers and academic books have been published on these stories. But when one engages community members it quickly becomes obvious that these stories are not known or used in local communities. This paper explores methods that were used by SARAO to identify what stories are being told by communities surrounding the SKA site and the process of incorporating this into an Astro tourism strategy. This process ensured that local communities were involved in telling their own stories, including them in the development of the area, Astro tourism and the preservation of cultural Astronomy in the SKA footprint area.

The LightSound Project: Observing Solar Eclipses with Sound

Allyson Bieryla[1], Sóley Hyman[2]

[1]Center for Astrophysics | Harvard & Smithsonian. [2]University of Arizona

Abstract

The LightSound Project is building 750 sonification devices for the upcoming 2024 North American solar eclipse. The device was designed to convert light to sound as a way to engage blind, low-vision, and non-visual learners in solar eclipse observing and data collection. The LightSound device can be used as an educational/outreach teaching tool and/or an eclipse observing device. The project is donating devices, at no-cost, to educators and organizations hosting events or looking to engage the public in eclipse science. The project has successfully deployed devices for past eclipses (2017 N. America, 2019 and 2020 S. America, 2023 N. America). We will give an overview of our project with the goal of making international connections in preparation for the many upcoming eclipses, including many African countries! The project is completely open source and we have a model where we run workshops to train participants how to solder while building devices that are then distributed to event organizers at no-cost. Our goal is to reach as many organizers as possible to stress the importance of accessibility as a planning tool and not an afterthought.

New Tactile Models of CMB for Inclusive Astronomy

Miss Constanza Farjo[1], Dr. Johanna Casado[1], Dr. Beatriz García[2]

[1]Universidad de Mendoza. [2]Universidad Tecnológica Nacional, Regional Mendoza

Abstract

Even when radiation comes from energy regions beyond the visible spectrum, Astronomy is mainly a branch of science based on the visual approach to celestial phenomena. This fact, the observation based on the perception of light, is a significant disadvantage for individuals with visual impairments or other styles of learning. One of the tools that facilitates participation or aims to achieve this goal is sonification; another is tactile modeling, allowing individuals in general to touch and explore replicas of celestial objects and other astronomical data such as spectra or light curves in a new way. Tactile models of astronomical images can be enhanced through the development of open-source code, offering benefits such as a freely usable, collaborative, and inclusive tool. With this new approach to representing images in 3D models and the use of libraries like PyVista, models can be exported to STL for printing. This would enable the creation of a tactile model suitable for 3D printing using data from astronomical observation present in images used for research, education, and outreach, and correlate color, intensity, or power with the height of printing. In this contribution, we will focus on the 3D creation of the Cosmic Microwave Radiation, using the COBE and WMAP images and the experience of using these tactile models in a framework of focus groups with able and disabled participants, specialists, and non-specalists.

Multimodal analysis in photometry and spectroscopy with Jupyter notebook

Dr. Johanna Casado[1], Dr. Beatriz García[2]

[1]Universidad de Mendoza. [2]Universidad Tecnológica Nacional, Regional Mendoza

Abstract

In recent years, there has been a growing emphasis on the multimodal approach to data analysis, which has important implications for the inclusion of individuals with visual impairments in research, education, and outreach. A multimodal display allows for the integration of different sensory styles when analyzing data, which can improve the overall effectiveness of data analysis. However, for this technique to be widely implemented, it is necessary for the scientific community to contribute to its validation and use in scientific discoveries. There are several tools available for sonification, but only a few of them have a graphic interface and a user-centered approach. This contribution focuses on the use of sonification for photometry and spectroscopy data, using a novel multimodal approach presented through a Jupyter notebook that follows the actual process of analysis. The object-oriented software sonoUno, which is centered on the user from the beginning, will be used, particularly its libraries, to produce the sonification and visualization of the data. The advantage of using the sonoUno libraries in a Jupyter notebook is that it enhances communication with other research groups.

Tales from the Zooniverse: Equity and Inclusion through Participatory Science

Lindsay House[1], Laura Trouille[2], Cliff Johnson[2,3], Samantha Blickhan[2], Chris Lintott[4], Lucy Fortson[5], Alex Andersson[6]

[1]University of Texas - Austin. [2]Adler Planetarium - Zooniverse. [3]Northwestern University. [4]University of Oxford - Zooniverse. [5]University of Minnesota - Zooniverse. [6]University of Oxford

Abstract

Participatory science (also referred to as citizen science) initiatives have emerged as pivotal tools for fostering equity and inclusion within the field of astronomy. These projects engage the public meaningfully in real research, increase trust in science by lifting the veil on the process of science, provide pathways into science careers, and more. Zooniverse, the world's largest platform for people-powered research, engages over 2.7 million people around the world in over 90 active projects across the disciplines, from astronomy to zoology, cancer research to climate science, arts and humanities. In this talk we highlight a few of the ways Zooniverse is used in service of equity and inclusion goals in astronomy; aligned with the IAU Office of Astronomy for Development efforts. We explore: 1) The Project Builder tools, empowering researchers worldwide to create crowdsourced projects for free. 2) Multilingual translations enabling global classification challenges, reinforcing the 'one-world/one-sky' ethos and utilizing astronomy for science diplomacy. 3) Educational resources like classroom.zooniverse.org, facilitating seamless integration of real research experiences into classrooms globally. 4) Collaborations with organizations engaging under-represented groups in STEM, utilizing Zooniverse projects and tools to further their objectives. We will share the lessons learned and open questions from these experiences.

Astronomy Accessible Software for All (AASA)

Sr. Sr. STEM Education Specialist Yasmin Catricheo[1], Staff Associate for Facilities Planning and Management Tim Spuck[2]

[1]Associated Universities Inc.. [2]U.S. National Science Foundation

Abstract

Astronomy Accessible Software for All is a North American Regional Office of Astronomy for Development (NA-ROAD) project. With support from the U.S. National Science Foundation (STEM+C 1640131), blind and low vision (BLV), sighted students and their teachers engaged in an authentic software development project to create tools and resources that make astronomy image analysis more accessible to BLV persons. The result was the Afterglow Access (AgA) software. AgA is a comprehensive browser-based astronomical imaging and data analysis software designed to work with screen readers and incorporates unique features that allow the user to experience images through sound, making astronomy more accessible to BLV persons. In addition, the software is available in both English and Spanish. The NA-ROAD has developed virtual and in-person training programs for those wishing to use the software themselves, or with their students and the general public. Join us for an AgA demo and learn how you can access it free of charge.

The work in community astronomy starts from within

Alysha Shugart

Vera C. Rubin Observatory. NSF's NOIRLab

Abstract

The framework for community astronomy must be founded on inclusive relationships based on mutuality and belonging. Collaborators that wish to form these relationships must begin the work within themselves and their working groups and organizations. Diversity, equity, and inclusion (DEI) programs at Rubin Observatory and NSF's NOIRLab create an infrastructure in the workplace for this effort to be undertaken, and compliment the external relationship building needed to drive a new model of community astronomy forward. Every person has a story related to finding their place in astronomy and in the world. They have stories of belonging or not belonging, or how they overcame barriers to be a part of astronomical research. This talk presents the drive at these organizations to build pathways in the workplace for DEI efforts. We develop policies to invite every member of the organization to spend work time in these spaces. We build a culture where efforts to inject DEI in all aspects of the organization are not thought of as secondary, but are a part of any staff member's work. The work being done internally extends outward, and reflects Rubin and NOIRLab in their external relationships. We discuss the process of creating a system that honors time spent in the community and building relationships as a part of work time. Staff of Rubin and NOIRLab allocate time to learn more about indigenous cultures in the local sites, foster discussions of inclusion and challenging worldviews, while organizational leadership rewards new partnerships and internal growth in DEI.

Embracing the Stars: A Journey into Astronomy Awareness and Inclusive Participation by Learners with Disabilities

Mrs Lindie Muller[1], Ms Landie Rose Muller[2]

[1]National Research Foundation. [2]New Hope School for Learners with Disabilities

Abstract

This study, to be presented by a 12-year-old learner with special needs (LSEN), explores the experiences that led to the development of a profound passion for astronomy awareness and participation. The research investigates the crucial role of inclusive environments and effective strategies that capture the interest of learners, promoting active engagement in astronomy exploration outside traditional educational settings.

The study highlights the transformative impact of a supportive environment and engaging approaches, revealing how the LSEN learner's initial fascination with astronomy evolved into a deep-seated passion. It emphasizes the significance of inclusivity, allowing learners of all abilities to feel empowered as they independently explore their interests.

Furthermore, the research delves into the ripple effect generated by the learner's heightened awareness, sparking conversations among impaired peers. This, in turn, resulted in a collective effort among the peer group to actively engage in science and astronomy-related programs.

Presented by the LSEN learner, this study aims to share insights with parents, educators, and stakeholders, emphasizing the importance of inclusive practices in cultivating a love for astronomy exploration among learners with special needs. The presentation also underscores the broader impact of individual awareness, demonstrating how it can inspire collective enthusiasm and engagement in science and astronomy programs within peer communities.

Scalable hybrid approaches to ensure equitable access for all sizes of astronomy events

Dr Mike Peel[1], Dr Dave Clements[1], Dr Vanessa Moss[2], Dr Glen Rees[3], Dr Elizabeth Tasker[4], Dr Emily Kerrison[2]

[1]Imperial College London. [2]CSIRO. [3]TFOM. [4]ISAS JAXA

Abstract

Hybrid and online events have demonstrated their ability to increase access to astronomy meetings over the last few years, with record numbers of online attendees. However, while this has improved inclusiveness, access has not always been equitable, with those able to attend the events in person often accidentally excluding online attendees; online attendees not able to gain the same benefits of in-person interactions; and uneven availability of both travel funding to attend in-person and computer equipment to connect online. This presentation will highlight the available tools, design, and social approaches that can be taken to make any event more effectively hybrid, with equitable access online and in-person, and how they can be scaled appropriately to match different event sizes while simultaneously reducing environmental impact. It will also include pointers for what has and hasn't worked well in past hybrid contexts, and explore the cost-benefit ratio for different approaches to hybrid meetings, pointing out ways of avoiding astronomy gatherings that cost the Earth.

"Astronomy Connects People"

Assist.Prof.Dr. Hürcan Tarhan

International Final University. Bahçeşehir University. TurkCimento Mesleki ve Teknik Anadolu Lisesi (Vocational School). Innovative Eduacators Association (Yenilikçi Eğitimciler Derneği)

Abstract

Astronomy can play a significant role in supporting individuals and organizations in their efforts towards equity and inclusion which can be used as a tool and accessible technology for educational outreach programs targeting underrepresented communities. Resources and education can be provided in schools with diverse student populations which was previously experienced by the researcher (https://cledi.unimib.it/project).

Workshops can be offered that highlight the inclusivity of astronomy and its relevance to various cultures including individuals with disabilities. It can be used as public engagement and community building where astronomy will be utilized to engage the public in discussions about diversity and inclusion in science. Events, lectures, and public talks can be organized from which organizations will benefit and actively work towards fostering diversity and inclusion.

International Collaborations will enable to share resources, knowledge, and opportunities on a global scale. Besides exchange programs will facilitate diverse participation in international projects. Astronomy can be used as a storytelling tool to convey the rich history of diverse contributions to the field which can inspire individuals from underrepresented groups to pursue careers.

On the other hand mentorship programs can connect individuals from underrepresented groups with experienced mentors in astronomy. Provided guidance and support will ensure a more inclusive and supportive professional environment.

By leveraging astronomy as a tool for education, outreach, research, and community-building, individuals and organizations can contribute to creating a more equitable and inclusive landscape in the field. This involves actively recognizing and addressing barriers while promoting diversity at all levels.

Equity and Inclusion in Astronomy: Directions for 2027; Striving for 2030

Dr Jake Noel-Storr

University of Groningen. accessastronomy.eu

Abstract

As I move to the chair position of the EC WG for the next triennium, I willho discuss the layout of our EC WG, which has the most members of any WG in the IAU, I will introduce our sub-working-groups and organizing committee at large members. I will outline what we hope to achieve as a working group for the next 3 years, and describe aspirational goals for equity and inclusion in astronomy by 2030.

Effective Diversity, Equity and Inclusion Programs

Prof Keshlan Govinder[1], Prof Mathilde Jauzac[2], Dr Kabelo Kesebonye[3], Dr Sinenhlanhla Precious Sikhosana[1]

[1]University of KwaZulu-Natal. [2]Durham University. [3]University of the Witwatersrand

Abstract

Diversity, equity and inclusion (DEI) are crucial for the efficient and effective functioning of any organisation. However, DEI has been under increasing criticism recently with many organisations (mainly in the USA) shutting down DEI programs. In addition, DEI efforts in South Africa (called transformation) have also had low-to-moderate impact. In this talk, we will share our experiences of running effective DEI workshops at the University of KwaZulu-Natal. In addition, we will draw upon Alvin Tillery's CREED model to try to explain the pitfalls of and backlash to some DEI efforts globally. Finally, we will share a controversial metric to measure the ``effectiveness'' of DEI programs.

Astronomy Education for Blind and Visually Impaired Students at the University of Nigeria Using Tactile Methods

Miss Ojima Ocheni, Mr Timothy Egbuim, Dr. Bonaventure Okere, Dr. Nnaemeka Onyeuwaoma

Centre for Basic Space Science and Astronomy (National Space Research and Development Agency), Nigeria

Abstract

To achieve the all-inclusive United Nations education, people with special needs must be engaged in science, technology, and education. This project engaged 50 undergraduate and postgraduate students with special needs at the University of Nigeria, focusing on blind people and students with visual impairment. The project reached out to 35 undergraduate students and 15 postgraduate students. The project adopted a workshop approach; tactile methods were used during the hands-on sessions, while lectures were presented using live talks and pre-recorded audio. The hands-on sessions of the project were on a touch of the universe, solar system modeling using beads, the galaxies, a feel of the moon, the telescopes, and the black hole. The workshop lectures were on the pale blue dot, astronomy for mental health and wellbeing, the solar system planets, and women in the space sector. The outcomes of the workshop were measured using pre-and-post surveys. The students filled out these surveys with the assistance of the workshop facilitators. The pre-workshop results of the survey showed 23% knowledge about space science and astronomy, while the post-workshop survey showed 75% increased knowledge of space science and astronomy. The workshop outcomes showed over 50% interest in Science, Technology, Engineering, and Mathematics (STEM). Astronomy and space science knowledge are not limited to race, gender, or people without disabilities. The outcomes of this workshop proved that education should be for all, as the curious mind is innovative.

Attendance isn't Enough: Metrics for Measuring the Impact of Equitable Practices in Astronomy Education

Dr Sophie Bartlett[1,2], Ms Shaaron Leverment[3], Dr Jen DeWitt[4]

[1]IAU Office of Astronomy for Education. [2]Cardiff University. [3]Association for Science and Discovery Centres. [4]Freelance Evaluation Consultant

Abstract

Promoting equality, diversity, and inclusion (EDI) is crucial not only for cultivating a diverse workforce with varied skills and expertise but also for empowering individuals to recognise their potential in astronomy and STEM fields, free from biased messaging and experiences. Despite the increasing prevalence of EDI initiatives and widening participation efforts, the assessment of their impact often does not reflect implementation. Current evaluations often focus solely on demographic reach without delving into the actual experiences of individuals.

Rather than limiting impact reports to numerical data and diversity metrics, it is important we move towards measures that effectively capture and demonstrate the depth of meaningful and inclusive experiences across diverse audiences. Adhering to the principle of "first do no harm", this shift requires a nuanced understanding of the experiences diverse groups have during engagement, outreach, and educational initiatives. Mere attendance should not be assumed as indicative of a positive experience.

This talk will focus on a UK programme funded by the Association for Science and Discovery Centres in partnership with the Science and Technology Facilities Council. The programme focuses on co-developing a logic model that defines, guides, supports, and evidences meaningful practice. This presentation will emphasise the significance of promoting EDI in astronomy and STEM engagement, defining "good EDI practice," providing evidence of EDI implementation, and proposing meaningful metrics for assessing impact. The focus is on moving beyond quantitative indicators to truly understand and enhance the quality of experiences within diverse communities engaged in astronomy and STEM activities.

Touch the sky. A multisensory planetarium to discover the Universe

Federico Di Giacomo[1], Stefania Varano[2], Rachele Toniolo[2], Marco Poloni[2], Juri Roda[2]

[1]INAF - Osservatorio di Astrofisica e Scienza dello Spazio. [2]INAF - Istituto di Radioastronomia

Abstract

This project is to offer a common perceptual and cognitive framework to all users, both sighted, deaf and blind or visually impaired, concerning the experience of observing the sky. The acoustic stimuli are intended to introduce a perceptual equivalent for blind and visually impaired users, while the haptic ones introduce quantitative features, which can only be known through instrumental observations.

The planetarium consists of a plexiglass hemisphere on which stars from the first to the fourth magnitude are represented each by a metal bar that, when touched, activates visual, haptic and acoustic stimuli. The represented features for each star are its apparent magnitude and its distance from us. We mapped the magnitude, the most commonly used feature in night sky observation, both on acoustic (notes at different volumes), visual (LED at different brightness) and haptic (number of bolts) stimuli. The distance of the star is mapped on a vibration, faster/slower for smaller/greater distances.

Through the integration of these stimuli, we have given a wide range of users the opportunity to immerse themselves in a unique and shared experience of the fascinating celestial panorama. The combination of thoughtful design, focused prototyping and thorough preliminary assessment demonstrated the effectiveness of this innovative approach. Thanks to this multisensory planetarium, we not only make the beauty of the night sky accessible, but also open new perspectives for inclusive science education, offering everyone, regardless of sensory abilities, the opportunity to explore and understand the vast universe around us.

Fostering a Diverse, Equitable and Inclusive workplace in the most remote Big City in the world

Dr Renu Sharma, Ms Asha Stabback, Prof Luca Cortese, Dr Brent Groves

University of Western Australia - ICRAR

Abstract

The International Centre for Radio Astronomy Research (ICRAR) was founded in September 2009 with the specific purpose of supporting Australia's bid to host the world's largest radio telescope and one of the largest scientific endeavours in history, the Square Kilometre Array (SKA). We are a joint venture between Curtin University (Curtin) and The University of Western Australia (UWA), with funding support from the State Government of Western Australia. ICRAR has research nodes at both universities with over 250 staff and postgraduate students and has been independently ranked in the top 5 university-based radio astronomy research centres in the world.

ICRAR is committed to creating a working environment and culture that is inclusive and provides equal opportunities, irrespective of race, gender, age, sexual orientation, culture and origin. We celebrate inclusion and diversity and believe gender equity is fundamental to an excellent workplace. We appreciate the experiences, skills and perspectives of all individuals and harness a collaborative environment.

In this talk, we outline the programs and initiatives established to foster a diverse, equitable and inclusive workplace as well as the challenges and opportunities. The inclusive culture has been recognised through the Gold Status in the Pleiades Awards, inspired by the UK's Athena SWAN program, and since 2018 the criteria for the Awards changed to reflect an expanded goal of equity and inclusion at all levels, and across all people in the astronomical community. ICRAR has also been named a Women in STEM Decadal Plan Champion.

Audio Universe: Making the Universe more Accessible Through Sound

Dr Christopher Harrison[1], Dr Ann Njeri[1], Dr Aishwarya Girdhar[1,2], Dr Anita Zanella[3], Dr James Trayford[4]

[1]Newcastle University. [2]LMU. [3]INAF. [4]Portsmouth University

Abstract

Audio Universe is a collection of tools and resources to support scientists, educators, students, and the general public to represent scientific data and concepts with sound (as well as with other senses). We do this to support: (1) scientific discovery; (2) engaging and immersive educational and communications content and; (3) increased accessibility to science. Here we will present how we have used sonification (turning data into sound) to create a sound-based planetarium show "Audio Universe: Tour of the Solar System" and complementary multi-sensory educational workshops. These were designed in collaboration with members of the blind and vision impaired (BVI) community, BVI specialist teachers, and their pupils. We present results from 291 audience evaluations from online viewers and audience members of planetarium showings. We find a strong appreciation from BVI and non-BVI audiences, with ~90% scoring 4 or 5 (out of 5) for both how useful and enjoyable the sounds are. We also present results from surveying planetarium and communication leaders known to have downloaded the show. We find international success for special events, for BVI audiences and for those with other special educational needs and disabilities (SEND; including sensory needs and learning difficulties). Finally, we will present the next steps to make these accessible approaches sustainable by providing communicators with their own sonification tools and guidance.

Outreach beyond the urban: multilingual and rural programs at the Indian Institute of Astrophysics

Dr. Niruj Mohan Ramanujam[1], Mr. Vikranth Pulamathi[1], Mr. Amoghavarsha Nagachandra[1], Mr. Dorje Angchuk[1], Dr. Shylaja B.S.[2], Mr. Punith Ramegowda[1], Dr. Chrisphin Karthick[1], Ms. SnehaLatha Karekal[3]

[1]Indian Institute of Astrophysics. [2]Jawaharlal Nehru Planetarium. [3](formerly at Indian Institute of Astrophysics)

Abstract

India is home to 100s of other languages. Like many countries in the global south, unfamiliarity with English is prevalent in socio-economically deprived communities and hence communication in local languages is imperative, especially in non-urban contexts. Though local science communication groups have been using regional languages for many years, research institutes have been slow to follow. In this talk, I will describe some of the efforts of the outreach programs of the Indian Institute of Astrophysics to bridge the linguistic as well as the urban-rural divides.

There has been considerable effort to create muilti-media content in multiple languages for astronomical events, including infographics, posters, audio and video, etc especially in the languages of the states where our observatories are located. I will discuss the challenges in obtaining translations that are both accurate and accessible, as well as those of dissemination. The latter stems from the fact that each state has its own language and hence needs us to develop extensive networks in each of them.

I will also describe our efforts in astronomy education in rural areas, mainly in collaboration with government agencies, which include working with numerous rural libraries, adding astronomy to the repertoire of local science communicators working in villages, and working with rural communities around our observatories. These efforts have also helped us unearth traditional astronomy knowledge in these communities, which would otherwise not be easily accessible. I will end by highlighting the importance of networking with local groups, and the ethical dimensions of such an exercise.

Supporting Neurodivergent Academics

Dr Veronica Allen

University of Groningen

Abstract

In recent years, greater understanding and public awareness of neurodivergent conditions like autism and ADHD has led to many adults discovering that their difficulties at work are caused by working in a neurotypical system with a neurodivergent brain. Neurodivergence is still commonly pathologized rather than accommodated, that is, neurodivergent people are told to "fix themselves" and fit into the system as it is, rather than have their environment adapted for them. This results in a much higher rate of burnout and job dissatisfaction as well as a loss of "out-of-the-box" thinkers in academia. Intersectionally, (cis-) women and girls were not commonly identified as neurodivergent until recently and there is a higher proportion of LGBTQA+ neurodivergent people, meaning that improving working conditions for neurodivergent people will also increase the inclusion of other minoritized groups. The good news is that job difficulties for ND people are often related to “traditional” working conditions and unwritten social rules. This means that the adaptations are simple to implement, though not intuitive for neurotypical people. While each neurodivergent person has their own specific individual needs, I will outline some practices and accommodations that institutions can easily enact in order to improve working conditions for neurodivergent and neurotypical people alike.

NRF's Research Communication Officer

Ms Mpendulo Sibiya

National Research Foundation

Abstract

Research Communications Officers are crucial in connecting researchers with the public by simplifying complex research findings for everyone to understand, which helps people grasp and value new scientific discoveries. The National Research Foundation (NRF) in South Africa actively promotes research and innovation interests locally and globally, building bridges between research communities, fostering mutual benefits and contributing to national development.

In this presentation, the NRF-RISA research communication officer will demonstrate strategies used in her role to communicate NRF-funded research effectively to stakeholders and the general public. This presentation aims to allow researchers at all levels to connect and showcase their work to the world through our communications and corporate relations. The presentation will highlight and also inform the researchers how to be featured in our next NRF Science Matters magazine, available at (https://www.nrf.ac.za/science-matters-magazine/), our weekly research nuggets website (https://www.nrf.ac.za/science-matters-magazine/research-nuggets/), our insightful social media channels and podcasts.

A Centre of Excellence in Planetary and Space Science and Technology (CESST) in Africa: report on the first phase of implementation

Prof Fulvio Franchi

Botswana International University of Science and Technology. Università degli Studi di Bari - Aldo Moro

Abstract

The project Focus on Africa Space Science and Technology 4 Future development (FAST4Future) aims at strengthening STEM in Africa Higher Education by promoting Planetary and Space Science and Technology (PSST) for sustainable growth and jobs creation. Africa is rapidly embracing the 4th industrial revolution and PSST has been identified as key area of investment to provide graduates and young scientists with both the necessary soft and practical skills to face 21st Century challenges such as digital innovation and higher skilled job creation.

The aims of FAST4Future are: i) To increase the accessibility to STEM in African; ii) To modernize existing PSST programmes; iii) To foster the internationalization and South-South collaborations; iv) to promote standardization of PSST in Africa.

To achieve these ambitious goals, FAST4Future created a Centre of Excellence in PSST (CESST) hosting a virtual platform (https://lms.cesst.org). Once fully implemented CESST will not only make PSST freely available to African students but will also coordinate collaborative actions to i) analyse the conditions needed to increase the participation of women in STEM in Africa; ii) modernise and harmonize PSST programmes in Africa; iii) promote the transfer of skills in key strategic areas of PSST.

The creation of a virtual platform within CESST opened new pathways for the dissemination of high-quality academic contents that will reach thousands of STEM learners across the continent and facilitate the access to STEM disciplines for Africans living in remote areas, conflict zones, and will increase the number of women in STEM.

Promoting Gender Diversity in Physics Education: The Case of WiPiSA in South Africa

Dr Joyful Mdhluli[1], Dr Katekani Shingange[2]

[1]Office of Astronomy for Development. [2]DSI/Mintek Nanotechnology Innovation Centre

Abstract

Despite being a developing nation, South Africa continues to face the challenge of underrepresentation of women and girls in physics education and related careers. This disparity is often attributed to the perception of physics as a male-dominated field and the lack of adequate support structures for female students.

This talk focuses on the efforts of the Women in Physics in South Africa (WiPiSA), a forum under the South African Institute of Physics (SAIP), to address the gender gap in physics education. We will give an overview of the organization's initiatives, particularly its focus on reaching underprivileged communities, to understand their approach to promoting and attracting women and girls to physics-related careers. The aim is to shed light on the potential of WiPiSA's work in contributing to a more diverse and inclusive physics landscape in South Africa. By communicating the efforts of WiPiSA, this talk plans to contribute to broader discussions on promoting gender equality in STEM education in developing countries.

An Analysis of the Principal Investigators of the European Space Agency Science Missions (1975-2024): Implications for Nationality and Gender

Professor John Zarnecki[1], Professor Arvind Parmar[2]

[1]The Open University, UK. [2]Mullard Space Science Laboratory, University College London

Abstract

We have collected data on the Principal (PI) and co-Principal Investigators of all relevant science missions within the European Space Agency's (ESA's) science programme since 1975. This now spans well over 400 scientists from most of ESA's current 22 Member States. The PIs have generally been selected through an Advisory Structure established to select missions and PIs based primarily on scientific merit. However, it is possible that biases, conscious or unconscious, might have been present in these selections. This study has aimed at investigating whether any such biases are apparent in these data. Results will be presented as well as recommendations for future actions in this area.

A Community Hub for Sharing Existing Resources and Methods for Including Blind and Low Vision People in Outreach Programs

Mike Simmons

Astronomy for Equity. Blue Marble Space Institute of Science

Abstract

Astronomy, the most accessible of sciences, is a natural introduction to STEM that encourages students to embark on STEM careers and serves as a gateway to STEM for isolated communities. But BLV people of all ages are largely excluded from astronomy programs and other STEM fields. Of eight million BLV in the US alone, one million are totally blind and one-third lack access to technology.

Thousands of volunteer outreach groups worldwide introduce astronomy and STEM to the public, but they are generally unaware that BLV people are not only interested in astronomy but that there are resources and proven methodologies for including them. Even when they learn of existing resources, they lack expertise and experience working with BLV and the means to source the materials. For experts and resource developers, a lack of interaction leads to resources and methods being reinvented in isolation.

While there are many individual BLV programs, there is no structured, interactive community where ongoing training, technical assistance, and support is free and available to everyone doing outreach. Astronomy for Equity has created an online community where astronomy outreach groups worldwide learn from experts and share their experiences with others. Experts can also interact and learn from each other, share the resources and methodologies they have created with outreach organizations, and get feedback from a diverse worldwide community of end users.

This community hub provides a model for community engagement projects in astronomy that Astronomy for Equity will be building in additional areas of astronomy outreach.

Under Other Skies: Dialogues of Different Cosmological Paradigms

Arianna Cortesi

Instituto de Física - Universidade Federal do Rio de Janeiro - Brazil. Observatory of Valongo - Universidade Federal do Rio de Janeiro - Brazil

Abstract

The sky is a shining record of the histories and mythologies of people of the world, drawn in the constellations, during the dark nights of pre-industrial societies. Yet, the boundaries of the constellations, approved by the IAU at its General Assembly at Leiden in 1928, reflect mostly the western cosmological paradigm. In a similar manner, scientific outreach is frequently reaching out only to a specific part of the world population, often excluding people living in extreme social vulnerability, victims of violence and prejudice, who are always fighting for their lives and for the right of living according to their traditions. In this talk, I will present the IAU/OAD funded project Under Other Skies, focused on ethno-astronomy, in particular on indigenous astronomy in Brazil. The project is co-created by indigenous researchers from a Maxakali Village, in the state of Minas Gerais, anthropologists and pedagogists of the Federal University of Minas Gerais, and astronomers and educators of the University of São Paulo, of the Observatory of Valongo and of the Nottingham University. This project was developed during pandemic, and astronomy served as a tool to face COVID-19 isolation in the indigenous village. The main deliverable of the project is a webpage, composed by the narrated stories and their illustrations, aiming to increase the indigenous didactic material available for primary schools inside and outside the village, and for the general public, fighting discrimination and defending the autonomy of indigenous education, giving institutional support and visibility to the newly created Aldeia Escola Floresta.

Diversifying STEM: Collaborative Initiatives at NRAO

Mrs. Danielle Rowland

National Radio Astronomy Observatory

Abstract

The Office of Diversity and Inclusion at the National Radio Astronomy Observatory (NRAO) actively supports broadening participation (BP) efforts in science, technology, engineering, and mathematics (STEM) using multiple approaches. In the United States, the fields of astronomy and physics do not reflect the demographics of the country's population leading to an underrepresentation of certain groups including, but not limited to, black, indigenous, and people of color (BIPOC), and gender and sexual orientation minorities. Diversifying the STEM workforce is a complex issue that cannot be solved by one organization alone, and systemic change must take place at several points along the STEM career pathway. Guided by a framework of collective impact centering equity (Kania et al. 2021; Kania & Kramer 2011), NRAO collaborates with external partners in several areas towards a shared goal of BP in STEM, particularly in astronomy, physics, and related fields. In this poster, I will overview three NRAO collaborative initiatives, at various stages of progress, that address BP in STEM by supporting students from underrepresented groups in different ways. These support methods include community and family outreach, access to informal and formal education, and providing research and training opportunities to gain experience.

Breaking Barriers: Bridging Gaps in Astronomy Education for Exceptional Learners in Ghana through the Teacher Training Program (TTP)

Mr Albert Kuntu Forson[1], Dr Asabre Frimpong Nami[1,2,3], Mrs Sarah Boamah[4], Mis Sarah Abotsi-Masters[1], Mr Joshua Kolongnia[1], Mis Christiana Kpakpo Donkoh[1]

[1]Promoting Astronomy in Ghana via School Visits and Astronomy Clubs (PRAGSAC). [2]African Astronomical Society. [3]Ghana Space science and Technology Institutes. [4]Ghana Education Service, National Robotics Facilitator Accra STEAM Centre

Abstract

Teaching astronomy to exceptional learners, particularly those from underrepresented groups facing diverse learning challenges such as disabilities or socioeconomic disadvantages, poses significant worldwide challenges. Ghana, specifically, lacks organized astronomy education programs for students and teachers in schools catering to exceptional learners, with a notable oversight of institutions for the blind and deaf despite previous efforts to enhance STEM education. Primary obstacle in Ghana's astronomy education for exceptional learners is the absence of accessible learning materials tailored to their specific needs. Traditional visual aids may not effectively serve visually impaired students, necessitating innovative and inclusive teaching methodologies, including tactile models, interactive digital platforms, and multi-sensory experiences.

To bridge this gap, we introduced the Teacher Training Program (TTP), providing astronomy workshops for grade 7-9 science teachers in schools for the blind and deaf across Ghana. The three-and-a-half-day residential workshop covers essential topics, aiming to equip teachers with hands-on activities for effective astronomy education for visually and hearing-impaired individuals.

This paper shares positive feedback and insights from participating teachers, along with encountered challenges, guiding future projects. Pre and post-evaluation analysis showed a substantial increase in participants' knowledge and skills, rising from 27.35% to an impressive 90.7% in teaching covered topics. Teachers demonstrated proficiency in using simple materials effectively, fostering enthusiasm for astronomy and dispelling long-standing myths. Additionally, 83.3% of participants indicated improved astronomy knowledge, highlighting the TTP's potential as a powerful tool in addressing astronomy equity and inclusivity in Ghana, contributing significantly to the country's growth and development by bridging the inequality gap.

AstroLingua: fostering equity in Astronomy through AI-driven accessibility

Dr Ana Paulino-Afonso

Institute of Astrophysics and Space Sciences

Abstract

At the heart of AstroLingua is the ambition to democratize access to the captivating field of extragalactic astronomy through the innovative application of artificial intelligence (AI) and natural language processing (NLP). This project, by providing descriptive analyses of celestial imagery for visually impaired individuals, bridges a crucial gap in accessibility, allowing a broader audience to engage with the mysteries of the cosmos. Utilizing the extensive Galaxy Zoo dataset, AstroLingua develops a comprehensive pipeline that integrates advanced image classification with NLP techniques to generate informative captions of galaxies. This dual approach not only enhances scientific understanding but also enriches public engagement and educational efforts by translating complex visual data into accessible formats. AstroLingua emphasizes the role of cutting-edge technology in expanding the frontiers of astronomy to all corners of society. By facilitating an inclusive dialogue about our universe, AstroLingua helps to pave the way for a more inclusive future in astronomical research and education.

Abstract

The two brightest satellite galaxies of the Milky Way are most commonly referred to as the Large and Small Magellanic Clouds. However, Indigenous communities around the world have known of the Clouds for centuries—long before the first Western explorers catalogued them. Furthermore, Ferdinand Magellan (for whom the Clouds are named) did not study these galaxies and was a controversial historical figure, considered by many communities to be a symbol of a violent colonial era. In this talk, I will outline several reasons why the astronomical community should rename these galaxies. I will also discuss an ongoing movement to rename the Clouds, including a proposed IAU resolution under consideration at this meeting.

IAU Advancing Inclusivity: Reflections on the Inaugural Diversity Meeting (NILAM) in Astronomy

ms Vilasinee (Fandora) Rung (Rynee)[1,2], Dr Storr Jake Noel-Storr[1,3]

[1]Co Chair for IAU sWG LGBTQAI+. [2]Apadilangit ; Universe Awareness Malaysia. [3]Groningen University

Abstract

The successful NARIT-IAU LGBT+ in Astronomy Meeting known as NILAM, co-organized by the International Astronomical Union (IAU) and the National Astronomical Research Institute of Thailand (NARIT), marks a significant milestone in fostering inclusivity within the field of astronomy. Collaborating with IAU Office for Astronomy Outreach (OAO) , IAU Sub Working Group on LGBTQ , NARIT and the International Training Centre of Astronomy (ITCA) orchestrated the inaugural LGBTQIA+ meeting in NARIT Chiang Mai.

Entitled "Building an Inclusive Astronomy Community: An LGBTQIA+ Meeting," the symposium aimed to provide a supportive platform for LGBTQIA+ astronomers to exchange insights, and deliberate on strategies for enhancing inclusivity within the astronomy community. Its main objective was to raise awareness among the broader astronomical community regarding the challenges encountered by LGBTQIA+ astronomers and to advocate for greater understanding and acceptance.

The meeting's success is underscored by its achievement of several key objectives. NILAM meeting sought to deepen understanding of the unique challenges faced by LGBTQ astronomers and to formulate comprehensive guidelines for both individual astronomers and institutions to foster diversity and inclusivity. Second main mission is to established a safe and nurturing environment wherein LGBTQIA+ astronomers could forge connections, share experiences, and cultivate a sense of belonging.

By spotlighting the collaborative efforts of IAU and NARIT, the symposium exemplifies a commendable endeavor to champion diversity and create a more equitable space within astronomy. Moving forward, it sets a precedent for future initiatives aimed at nurturing a welcoming and inclusive environment for all individuals within the astronomy field.

Improving diversity, equity and inclusion one hashtag at a time

Cheyenne Polius[1,2], Ashley Walker[1], Caprice Phillips[1]

[1]Black In Astro. [2]LUNAA Journeys

Abstract

Social media has transformed the way we connect, tearing down global barriers and fostering a sense of community through its diverse communication channels. Black In Astro, a grassroots organisation, has seen the power of this as we have reached tens of thousands of people from just one social media hashtag. Black In Astro was created in 2020 after widespread news of police violence in the United States. It was a simple yet powerful social media campaign kicked off by African-American Planetary Scientist, Ashley Walker, that encouraged Black people in Astronomy to share their experiences using the hashtag #BlackInAstro. Since then, it has grown into an organisation that supports Black people in space-related fields and amplifies the voices of up and coming space professionals all over the world. Social media has been the primary tool for sharing our events, news and avenues for tangible support and has helped Black In Astro gain recognition from big names like NASA, Nature and the Royal Astronomical Society. This talk will focus on how social media can be a powerful tool for the improvement of diversity and inclusion in astronomy and will dive into how Black In Astro has leveraged this tool to reach countries that may not have been reached otherwise. Our annual week of virtual activities, #BlackSpaceWeek, also powered by social media, showcases work from Black researchers and professionals in our global community. This talk will also highlight some of the amazing discoveries of our members including from Europe, Africa and the Caribbean.

Utilizing the Science of Science Communication to Engage Vulnerable Audiences in Astronomy: Insights from the Soha Astronomy Volunteer Network

Fatemeh Bonyadi

Allameh Tabtab'i University / UNESCO chair on science communication

Abstract

In the Soha Astronomy Volunteer Network, we employ two science communication frameworks: 1) the classic Audience Pyramid in science communication, and 2) the Engagement Model for public involvement in science.

Audience Pyramid: Our science communication employs a four-tier Audience Pyramid. The base represents the lay public, followed by the interested public, the involved public, and finally, scientists.

Engagement Model: Over time, the Participation model has proven most effective in engaging individuals in science. We utilize this model to elevate individuals within the Audience Pyramid.

We encourage non-specialist public participation in hosting astronomy night events for vulnrble communities. Collaboration with individuals from various backgrounds, such as artists, athletes, and celebrities, enhances the engagement of vulnrable communities in these events. Our approach targets communities with special needs, fostering a sense of community and inclusion.

Our experience has shown that involving the lay public in a scientific event that incorporates play and emotional engagement can enhance community involvement and raise their awareness and serve as a tool to elevate them within the Audience Pyramid, turning them into interested audiences.

We collaborate with psychologists to tailor events to the specific needs of the target audience. Finally, we invite participants (both lay public who assist in event organization and target audience) to share three significant insights about the event. These insights may include newfound knowledge about astronomy or specific needs identified within the target community, which can be addressed and adjusted. Feedbacks from the participants indicates that both groups become interested in astronomy.

AstroAccess: Advancing Disability Inclusion in Space Exploration

Anna Voelker[1], Caitlin O'Brien[2]

[1]SciAccess, Inc.. [2]SciAccess, Inc. | The Ohio State University

Abstract

AstroAccess is a non-profit initiative dedicated to making space exploration accessible to all people. AstroAccess conducts zero-gravity missions in which Disabled scientists, veterans, students, athletes, and artists (the "AstroAccess Ambassadors") from around the world perform demonstrations onboard parabolic flights, as the first step in a progression toward flying a diverse range of people to space. Since its founding in 2021, AstroAccess Ambassadors have participated in six zero-gravity flights and three analog astronaut missions. Ambassadors experience weightlessness, test microgravity accessibility tools, and investigate how physical environments onboard spacecraft can be designed so that all astronauts, regardless of disability on Earth, can work and thrive in space. AstroAccess Ambassadors use their platform to act as public advocates for global disability access in astronomy and the STEM fields.

This session will share findings from AstroAccess Flight 2, which took place in Houston in December 2022. Conclusions will be shared from technologies tested onboard the zero-gravity mission, including tactile graphics for non-visual navigation, microgravity sign language comprehension, mobility demonstrations, and many more. AstroAccess Ambassadors have also conducted astronomy research in zero-gravity to demonstrate that people with disabilities can successfully perform astronomical and scientific research in space environments. This session will showcase essential accessibility considerations and share best practices on inclusive space station design, calling for a change in industry standards.

Participants will gain a novel perspective on space accessibility and universal design, which are intended to enrich space research and pave the way for a more equitable future, on earth and beyond it.

ASTROx Dark Sky: Integrating Astronomy Education for Sustainable Practices and Community Engagement

Exodus Chun-Long Sit

President of Starrix Hong Kong. National Astronomy Education Coordinator (Chair of Hong Kong, China). Co-National Outreach Coordinator (Hong Kong, China)

Abstract

The field of astronomy education has recognized the pressing need to incorporate sustainability practices into classroom learning, going beyond traditional teaching methods. This presentation explores the ASTROx initiative, an interdisciplinary approach that merges astronomy with other academic subjects, aligning with the Sustainable Development Goals. Highlighting a student-led social innovation project, this talk showcases how dark-sky advocacy and science communication can address real-life challenges within communities. The students employed a range of innovative techniques, including outdoor classrooms, design thinking lessons, and hands-on experiences to raise awareness about the detrimental effects of urban light pollution. By integrating astronomy education into interactive classrooms, students not only grasp the fundamental concepts of the universe but also actively contribute to sustainable practices and community engagement. This presentation offers insights into the effective integration of astronomy education, empowering students to become informed advocates for dark-sky preservation and environmental stewardship.

Latest developments at the Aoraki Mackenzie International Dark Sky Reserve

Prof John Hearnshaw

University of Canterbury, Christchurch, NZ. Aoraki Mackenzie International Dark Sky Reserve board.

Abstract

In 2012 the Aoraki Mackenzie International Dark Sky Reserve became the first dark-sky reserve to receive DarkSky accreditation in the southern hemisphere. At 4367 sq km, it is one of the larger reserves in the world. The reserve encircles Mt John Observatory, NZ's premier optical observatory near Lake Tekapo. A very active astrotourism programme operates in the reserve, with at least nine companies offering guided dark-sky tours.

In 2022 the local Mackenzie District Council replaced all of the streetlights (just over 1000) in the district with 2200 K LEDs, including those on lampposts as well as lower bollards. A proposal supported by the District Council to extend the reserve eastwards to include the small town of Fairlie is being pursued in 2024. If approved, the area will increase to 7339 sq km, which will be the second largest reserve world-wide.

A dark-sky Starlight Conference is planned in the reserve in October 2024 (https://starlightconference.org.nz), which will enhance the reserve's reputation as one of the preeminent dark-sky reserves globally. An earlier Starlight Conference in 2019 led to the establishment of the Dark-Sky Network NZ (https://dsnnz.org), an organization giving support to about two dozen existing (currently six) and aspiring (about 20) dark-sky communities in New Zealand.

In January 2024 a petition was made to the NZ Parliament to introduce national legislation to protect the whole of New Zealand from light pollution.

[1]Laboratory of High Energy Physics and Astrophysics, Department of Physics, Cadi Ayyad University, Semlalia Faculty of Sciences, BP 2390, Marrakech, Morocco. [2]Oukaimeden Observatory Director

Abstract

Abstract :
We are interested in studying the site of the observatory of oukaimeden. At in recent years, the Oukaimeden observatory has hosted several instruments to measure the quality of the sky in terms of astronomical observations. Among these instruments, we can mention the SQM (Sky Quality Meter), widely used to evaluate night sky brightness NSB from the bottom of the sky and thus estimate the level of light pollution above Oukaimeden. In addition, there are other interconnected instruments, such as the TESS photometer of the Star4All consortium, also insturment CoSQM which was recently install through a collaboration with the University of Sherbrooke, Canada.

This is part of the Atlas Dark Sky project, aimed at studying the evolution of light pollution in the Toubkal Dark Sky Reserve precisely the geographical center of reserve "Oukaimeden Observatory".

Keywords : SQM - TESS - CoSQM - NSB- OUCA-ADS

Night Sky Brightness and the Solar 10.7cm flux

Dr John Barentine[1,2], Dr Emilio Falco[2], Dr Albert Grauer[3,4], Dr Hannes Gröller[3]

[1]Dark Sky Consulting, LLC. [2]Southern Chapter of DarkSky International. [3]Catalina Sky Survey, University of Arizona. [4]DarkSky International

Abstract

Mitigating the impact of artificial light at night (ALAN) on observatory operations requires accurate knowledge of night sky brightness (NSB) over long time scales. Such data are helpful not only to observatories, but also to the public at large.

We present an analysis of NSB over 4-6 years at four sites with differing night sky quality: Chiricahua National Monument, Arizona; Cosmic Campground, New Mexico; Prineville Reservoir State Park, Oregon; and Mount Lemmon, Arizona. The first three sites are far from population centers; Mt. Lemmon is near Tucson, with ~1000000 inhabitants in its metropolitan area. Time-series data were acquired at the zenith with Unihedron Sky Quality Meters (SQMs).

We developed Python software to analyze SQM data. Factors that contribute to the natural component of NSB vary seasonally but are poorly characterized. Our analysis aims to characterize these factors. Cyclical and stochastic variations in solar flux (SF) are a significant influence. The SF started rising at the beginning of the current Solar Cycle 25 in the second quarter of 2020 and continued rising through February 2024, when it reached twice the level in 2020. We find that as the SF doubled, NSB also rose but at a more modest rate of about 20%.

Continued monitoring is necessary to further confirm our conclusions and to follow the expected decrease in the SF by 2025. We plan to continue this effort and extend it to analyze the measurements that we will obtain with a 30-site SQM network spread over Southern Arizona.

New Approach Reducing Skyglow on Astronomical Images in Regions Affected by Heavy Advertising and Indoor Lighting Pollution

Mr Vladimir Pashkovsky[1], Mr Stanislav Karpikov[1], Dr Nicolai Shatsky[2]

[1]StealthTransit Laboratories, StealthTransit, Germany. [2]Sternberg Astronomical Institute, Moscow State University, Caucasus Mountain Observatory, Russian Federation

Abstract

Protecting the dark sky through the installation of full-cutoff outdoor lighting is approaching the limit of its effectiveness. Recent research findings indicate that a significant portion of light sources, including facade lighting and side emissions from indoor lighting, cannot be adequately restricted or mitigated using full cutoff. Moreover, the annual increase in light pollution exceeds previous estimates by several folds, reaching 9.6%. Addressing light pollution under such circumstances requires innovative approaches.

In this study, we analyze the requirements and discuss the possibilities and limitations of a fundamentally new engineering solution aimed at mitigating all types of lighting sources. It achieves a reduction in light pollution within the telescopes' field of view by up to 2 magnitudes, nearly completely neutralizing the outdoor lighting glare produced by a city with a population of 100,000 located 30 km away from the observatory.

The solution comprises an integrated system wherein lighting sources, such as outdoor fixtures, outdoor advertising, facade and indoor lighting operate synchronously in pulse mode at frequencies of 150 Hz and higher. It has been demonstrated that these pulsations are imperceptible to the human eye and do not have hidden effects on the nervous system. The second component is an active shutter module installed on the telescope, which operates synchronously with the lighting sources in anti-phase with the light pulses, blocking the exposure. Digital synchronization ensures accuracy and manages the phase to accommodate delays and reflections. The presented method was tested under operational conditions by StealthTransit Laboratories.

Radio Frequency Interference at the ALMA Observatory

Dr. Giorgio Siringo[1,2], Dr. Sean Dougherty[1]

[1]Atacama Large Millimeter/submillimeter Array - ALMA. [2]European Southern Observatory - ESO

Abstract

We present work done by the Joint ALMA Observatory Spectrum Management Office (JSMO) preventing/mitigating ground- and space-based RFI at ALMA. ALMA's spectrum extends above 100 GHz, a characteristic that provides natural RFI protection, but makes monitoring/identification of RFI very difficult. The ALMA site on the Chajnantor altiplano is surrounded by a number of other observatories, and there is risk of interference due to RF emissions from these other observatories (and vice-versa). One task of the JSMO is to coordinate operations that may interfere with other observatories, e.g. holography transmitters for surface assessment or the ALMA artificial calibration source. The cloud-profiling radar (CPR) onboard the CloudSat satellite has been a source of concern because it has sufficient power to damage an ALMA receiver in case of direct beam-to-beam alignment between the CPR and an ALMA antenna. CloudSat was recently decommissioned, finally eliminating this concern. However, we learned a lesson: it would have been much more efficient if the satellite operator had turned off emissions for the few seconds it was passing over the observatory site, rather than the observatory being forced to mitigate the risk, a task which produced a significant loss of ALMA observing time. With RFI from satellites an ever increasing challenge for RFI management strategies due to the growing number of satellite constellations, the JSMO is planning to use ALMA to track satellites and measure the emissions to better understand the challenge presented by satellite constellations.

Raising Dark Sky tourism and Light pollution awareness : The Amazing Dark Sky in Thailand

Matipon Tangmatitham

National Astronomical Research Institute of Thailand (NARIT). International Training Center in Astronomy under the auspices of UNESCO (ITCA)

Abstract

Since 2021, over 110 sites in Thailand have been designated as dark sky areas by the National Astronomical Research Institute of Thailand (NARIT). In addition to the focus on preserving pristine and pollution-free sky, Amazing Dark Sky in Thailand project also focus on the raising awareness on the issue of light pollution and promoting “Dark Sky tourism” as an engine for sustainable socio-economic development. To support these goals NARIT also launches other programs aimed to compliment these effort. The "astro guide" training program seek to train, evaluate, and certify astronomy outreach personnels that will operate in these dark sky areas that is vital to the sustainability of the tourism of the dark sky preserves. In order to promote the dark sky projects and raising awareness in the public sector, "Dark Sky Star Party" are held annually receiving around 2,000-3,000 visitors. However, the most important milestone of all, is the spinoff event “Starry Night Over Bangkok” where a star party is held in the middle of sprawling Thailand’s capital city in order to promote awareness in astronomy and astrotourism. In a single night, a total of 12,000 participants attended the event, making this single event the largest stargazing event ever been recorded. This is the real testament to the success of the the program in promoting appreciation in astronomy in the public sector.

Phatima ka ti Nheleti (Shine of the stars)

Amirah Izidine, Nicholas Romero, Cristóbal Castro

Universidad de Santiago de Chile

Abstract

Human settlements and cities have expanded in recent years, causing environmental issues such as light pollution. This problem is often overlooked, yet has harmful effects on both our environment and circadian rhythm. Our project, "Phatima ka ti Nyeleti" (Shine of the Stars in changana), aims to address this issue by providing better public space illumination while reducing the negative impact of light pollution. Our innovative luminary, composed of recyclable materials and powered by renewable energy sources, will provide lighting to rural areas while preserving the night sky and the environment. By reducing electricity usage and costs, we believe we can significantly improve the situation. The name of our project reflects our dedication to preserving the night sky while illuminating the world.

According to the International Energy Agency's 2021 study, approximately 600 million people in Africa lack access to electricity, with only 44% of Mozambique's population having electricity. Our solution will benefit Africans by addressing their needs, reducing these percentages, and creating job opportunities throughout the design and renewable energy development process.

In conclusion, our project has the potential to pioneer an eco-friendly and modern approach to illuminating present and future settlements while minimizing the damaging impact of light pollution.

Abstract

FreeDSM (Free Dark Sky Meter) is an IoT photometer for citizen light pollution monitoring, developed in the context of the Gaia4Sustainability project (https://gaia4sustainability.eu/language/en/gaia-4-sustainability/), intended to develop a robust, reliable, and straightforward framework for estimating the night sky brightness. Among environmental problems, light pollution is among those with a fastest growing in recent times, particularly in highly populated areas and developed countries. This is a global issue that very seriously affects the natural day-night life cycle and has a deep impact on the well-being of many living species, including humans, even contributing to fossil fuel combustion and the aggravation of climate change.

FreeDSM is based on an ESP32 microcontroller, which is a cheap and low-consumption component that integrates different sensors. The ESP32 is powered by Tasmota, a well-known open software home assistant tool that integrates basic logic for many commercial sensors. Interestingly, it has a rechargeable battery, which allows different device use ways. Our group has developed a low cost, easy to handle, open software and hardware solution with the aim to empower individuals to take action to reduce the amount of unnecessary outdoor lighting, spreading the word on night sky protection and popular access to astronomy at the same time.

The project is now in a commercial feasibility study phase and we here intend to summarise its current status, achievements and future plans. Either from homes, schools, parks or hospital roofs, advantageous possibilities are to be offered to NGOs, administrations, stakeholders and individuals for easy and cheap dark sky surveyance.

Dark Sky Successes in Southwest Texas

Dr Teznie Pugh[1,2], Stephen Hummel[1]

[1]The University of Texas at Austin, McDonald Observatory. [2]AAS Committee for the Protection of Astronomy and the Space Environment

Abstract

In March 2022, McDonald Observatory partnered with four counties, six municipalities, a National Park, multiple State Parks, the Nature Conservancy in Texas, and two Mexican land protection agencies to found the Greater Big Bend International Dark Skies Reserve. The Reserve encompasses almost 15,000 square miles (24,140 square kilometers) in southwest Texas and northern Mexico.

The Reserve application represented a formalization of decades of effort in the region. In the years since the certification by DarkSky International we have continued these efforts resulting in two other Texas counties adopting lighting ordinances that meet the standards outlined in the Reserve's Lighting Management Plan and in the Texas Department of Transportation adopting new lighting standards in the region.

Together the 6 counties now covered by updated ordinances since 2020 total 24,291 square miles, or 39,092 square kilometers, with a total population of 50,431 (2021 census). Two of these counties contain a substantial number of oil and gas installations. Here we discuss our trials and successes in getting the ordinances in place and in educating the regional residents and operators about the ordinances, and discuss the breath of the collaboration involved

Abstract

The problems of light pollution and the unprecedented issues raised by its management in the many territories currently concerned with the preservation of the nocturnal environment are complex real-world problems. This complexity and the need to grasp these issues in their entirety are now forcing researchers to go beyond traditional disciplinary approaches to truly interdisciplinary studies at the interface between the sciences of the Universe, the environmental sciences and the social sciences. In order to organize this production of interdisciplinary knowledge and encourage its transfer to territorial action, the French National Center for Scientific Research (CNRS) has created in 2021 the Nocturnal Environment Observatory (NEO — https://observatoire-environnement-nocturne.cnrs.fr/en/). Through its research programs, actions and partnerships with various territories, the Nocturnal Environment Observatory brings together a large community of scientists from different disciplines and institutions (social and natural sciences, sciences of the Universe, engineering and environmental physics), experts from different and complementary professional fields, as well as agents at the service of protected area management structures and territorial projects. Through the case study of Reunion island — a densely inhabited area under severe ecological constraints — we will present the objectives, the analytical framework, the tools and the methods of the NEO. We will show the concrete contributions to territorial action of a radically interdisciplinary research on the nocturnal environment, a socio-ecosystemic object built on the foundations of the Dark-sky movement, and therefore owes much to the work of the astronomical community since the second half of the 20th century.

Radio Frequency Management at the SKA Observatory

Mr Federico Di Vruno, Mr Treasure Nkawu, Dr. Paul Van der Merve, Dr. Antheun Botha

SKA Observatory

Abstract

Radio frequency interference is one of the most critical aspects for a radio telescope. This can be divided into two large groups: Internal and External RFI. Internal RFI is considered all the radio noise produced by the telescope electronics (drives, high speed digitization, data transport, etc) and the activities we need to do on site (construction, maintenance, visits, etc). External RFI is defined as all the radio signals that come from sources outside of the control of the observatory. The SKAO takes a wholistic approach to RFI management, looking carefully on our internal RFI generation trough the EMC/RFI group and to the external RFI through the Spectrum Management group.

This presentation will discuss how we have implemented this approach, successes, challenges and current status.

KID: EU Interreg North-Sea Light Pollution Monitoring

Jake Noel-Storr

University of Groningen

Abstract

The aim of the KID project was to develop methods for a long-term measurement network of sky brightness in the tri-lateral Wadden Sea region. For this purpose two pilot places have been chosen in each of the three participating countries (NL,GE, DK) representing a dark and light polluted sky. Additionally a measurement platform has been set up on a mobile observatory offering easy comparison of different detectors under varying skies. In the project so far we tested 13 different detectors ranging from single channel devices (SQM, TESS, TASS, SG-WAS), RGB- or b/w-camera based systems (SQC, RP, Ricoh-Theta, Oculus), meteor camera systems (Allsky7, Fripon) and pure spectral systems (Alpy 600, LHires-II, RAMSES). For non weather-proof detectors a special multi-purpose housing was developed. For all camera based systems a RaspberryPi based platform for image acquisition, housekeeping-data, remote access via 4G standard as well as analysis and data transfer has been set-up. We present our results to date here.

Searching For Potential Locations For Astronomers To Establish Dark Sky Camps In Iran

Mr Matin Najarzadeh[1], Mrs Sahar Momeni behjatabadi[2]

[1]University of tehran,iran. [2]Researcher,tehran,iran

Abstract

The purpose of this research is to identify prospective locations for semi-professional and amateur dark sky camps in Iran. This study employs a descriptive research design that gathers data in the field through application. Local experts, tourist specialists, and amateur astronomers made up the research's statistical population.

In this study, 25 factors in 8 recommended regions in Iran for semi-professional and amateur sky observation have been examined and compared using questionnaires and interviews. This allows one to determine the optimal locations for setting up appropriate facilities and constructing a dark sky camp.

It was both amateur and semi-professional. The height above the open water's surface, the sky's upper bound, seismicity, Among the factors measured in this research are the quantity of dust on the horizon, the level

of light pollution, the number of clear and cloudless nights throughout the year, access roads, and security of the study region. The project aims to explore the following eight locations: Star Valley in Qeshm Island in Hormozgan Province, Viligia Peak in Jasb Village in Markazi Province, and Seghale Desert in Semnan Province. Based on the findings of this study, these three locations can be recommended as good sites for the development of specialist infrastructure to cater to astronomy enthusiasts traveling there.

The effect on the dark skies from LED lighting from towns and cities both local and beyond the horizon in the UK Malvern Hills area of outstanding natural beauty.

Dr Christopher Baddiley

BAA CfDS

Abstract

This presentation summarises the work and conclusions of a long-running dark-sky measurement project at the author's UK rural-located observatory, to study the effects of the introduction of LED outside lighting and from changes in the weather. The monitoring uses a mast-mounted sky quality meter (SQM) recording at two-minute intervals every night, and a fisheye lens camera recording on the darkest nights, now with over 10 years of data. The SQM is tilted from vertical slightly north to avoid the Milky Way.

Conclusions: the clear night sky brightness smoothly decreases during the night until hours before dawn. Histograms show a reduction in the number of dark nights over the period and the frequency of reaching the darkest values, attributed to changes in the weather. The colour change from orange to white from LED lighting is clearly shown in the camera images, and sky domes above the horizon can be seen from identifiable cities up to 150 kilometres away, also shown by plotting isophote contours. The darkest zenith brightness remains the same over years, (magnitude 21.1 mag/arcsec2 at the observatory location), but the horizon brightness has increased greatly. The background light-pollution contribution across the sky follows a simple empirical curve.

LEDs are directional if properly mounted with full horizontal cut-off, but the blue content causes far more scattering in the sky, together with increased brightness and reflection from the ground. This unfunded voluntary work has been used to advise policy makers, including the highways agency and the institute of lighting professionals.

Lunar Science and Policy – the IAU Working Group on Astronomy on the Moon

Richard Green

University of Arizona. IAU CPS

Abstract

The Moon provides a unique platform in the inner Solar System for three types of astronomical observations: low-frequency radio in the shielded zone on the far side; infrared observations, particularly of deviations from the blackbody of the Cosmic Microwave Background and of exoplanet atmospheres with near-continuous orbital coverage; and detection of gravitational waves on a low-seismicity stable platform. Operations in suitable sites are incompatible with many other planned activities on the Moon, such as landings and launches or extraction of water ice and minerals. The IAU Working Group consists of mission science advocates/PIs, spectrum managers and policy/space law experts. The near-term objectives are to identify and prioritize the sites required for each type of mission, to translate the good intentions of protecting the shielded zone from radio-frequency interference into practical implementations, and to create an internationally agreed system of coordination and protection of sites for specific uses. The IAU is actively engaged with the ITU, UN COPUOS and other scientific organizations to provide a complementary and unified approach to protect options for astronomy.

The effect of the airglow and the solar activity on the night sky brightness measurements

Laura Costa[1], Eduard Masana[1,2,3], Salvador J. Ribas[1,4]

[1]Departament de Física Quàntica i Astrofísica (FQA), Universitat de Barcelona (UB), 08028 Barcelona, Spain. [2]Institut de Ciències del Cosmos (ICCUB), Universitat de Barcelona (UB), Martí i Franquès 1, E-08028 Barcelona, Spain. [3]Institut d'Estudis Espacials de Catalunya (IEEC), Esteve Terradas, 1, Edifici RDIT, Campus PMT-UPC, 08860 Castelldefels (Barcelona), Spain. [4]Parc Astronòmic del Montsec, FGC, Ager, Spain

Abstract

This work analyses how airglow and solar activity influence the Night Sky Brightness (NSB) measurements and the study of Artificial Light At Night (ALAN). We study data measured by TESS, SQM and FreeDSM photometers and calculate the NSB of different locations using the spectral response of the instruments and spectra measured by the SAND spectrometer.

Two of the most widely used photometers, TESS and SQM, present a very different spectral response at wavelengths with high airglow emission values, which may lead to an incorrect measurement of ALAN due to natural contributions. We analyze spectra from dark and urban locations with the spectral response of these two photometers and for the new FreeDSM photometer, focusing on Parc Astronomic del Montsec (Lleida, Spain), as it is the only location where we have data for all the instruments.

We study the effect of adding a factor of airglow radiance to dark spectra to see how it influences sky brightness measurements. We subtract the airglow contribution of the spectra measured at dark locations and then add different contributions of the airglow spectra provided by the Cerro Paranal Advanced Sky Model (Deverchère et al. 2022, Jones et al. 2013).

In addition, we are trying to correlate the intensity of airglow on Earth with solar activity through TESS and SQM measurements. We compare the time evolution of the data with the time evolution of the solar flux. In most cases, TESS and SQM data present a decrease in brightness during the period of minimum solar activity.

Dark Skies Protection at NSF's NOIRLab Observatory Sites in Chile

Dr. Constance Walker[1,2], Dr. Guillermo Damke[3,2], Dr. Rodolfo Angeloni[4,2], Mr. Javier Sayago[5,2]

[1]IAU CPS. [2]NSF's NOIRLab. [3]Cerro Tololo Inter-American Observatory. [4]Gemini Observatory.
[5]Oficina de Protección de la Calidad del Cielo del Norte de Chile

Abstract

Since the introduction of urban illumination more than a century ago, the visibility of the pristine starry night sky has been gradually fading.
A next step in the protection of the night sky for NSF's NOIRLab observatory sites in Chile was to form an Office of Observatory Site Protection (OOSP).

The OOSP has a few key areas of focus on which the Dark Skies Protection (DSP) Research Group works. During the last few years, the DSP Group, alongside the Office for the Protection of the Skies of Chile (OPCC), has been working with communities near the observatories to light responsibly, to reduce the sky glow seen from Cerro Pachon and Cerro Tololo, and improve the effectiveness of the lights in the communities and incorporate energy savings. The OPCC has 20 years of experience working with the municipalities on lighting laws and lighting evaluations and replacement recommendations and is a partnership between major optical observatories in Chile.

The DSP group also provides, at consistent intervals, quantitative measurements of the night sky brightness at NOIRLab locations. Led by OPCC, the group has completed an external lighting inventory at NOIRLab locations. Led by the University of La Serena, the group is involved in the installation of a regional network of light pollution measuring devices. They have also engaged the public in light pollution awareness activities.

During our presentation we will discuss our current and future efforts to monitor and minimize light pollution around NOIRLab facilities, so their full scientific potential can be realized.

The synergy between astrotourism, dark sky conservation and astronomical outreach

Ms Nalayini Davies[1,2], Mr Ruskin Hartley[1]

[1]DarkSky International. [2]Royal Astronomical Society of New Zealand

Abstract

Astrotourism and its attendant economic benefits are growing rapidly. These are made possible by the presence of dark sky places and the ability to deliver astronomical outreach. To be sustainable then, astrotourism should support ongoing dark sky conservation and the continued development of astronomical outreach. The key findings from a recent DarkSky International survey of dark sky places worldwide, and the emerging principles of responsible astrotourism, will be shared to raise awareness and to obtain feedback.

We present findings from a recent survey of 209 international dark sky places, which reveals a rapid growth in astrotourism, that delivers an escape from urban nighttime glare and the breathtaking experience of a pristine natural night sky. Dark sky destinations are found to offer unique opportunities for private economic development, thereby drawing attention to the potential for stargazing to be a driver of sustainable growth in remote and often overlooked regions. The survey highlights the increasing interest and investment in such dark sky places. It also provides insights into the economic benefits that astrotourism operating in dark sky places can bring to local communities.

The talk will explore the evolving principles of responsible astrotourism, with economic benefits delivered whilst the environment is preserved, indigenous cultures and local society are respected, there is compliance with local regulations, and light is used responsibly.

Involvement of Radio Astronomy in the Regulation of Lunar Communication

Dr. Gyula I. G. Jozsa

Max-Planck-Institut für Radioastronomie

Abstract

Astronomers brought Moon missions with the aim to conduct radio astronomical experiments to consideration at the International Telecommunication Union (ITU) at a time when they were still a vision. As a result, radio astronomy enjoys special protection in a volume shielded from radio services on and around Earth. Today, the interest in the Moon in the context of space exploration, in research and also commercial, increases. Moon missions with the potential of bringing radio astronomy to the Moon are no longer fiction but reality. But also other missions are planned and the required increased communication make an update of the regulations necessary. Astronomy should not miss to contribute to this process, in order to ensure that future astronomy protection on the Moon aligns with its scientific needs. I will discuss the regulatory processes at the ITU level and give a brief overview of activities to protect radio astronomy in the Shielded Zone of the Moon.

AAS+IAU = D&QS: National and International Activities to Protect Dark and Quiet Skies by the AAS Committee to Protect Astronomy and the Space Environment

James Lowenthal

Smith College

Abstract

Spurred by the advent of large low-Earth-orbit satellite constellations and building on our history of combatting ground-based light pollution, radio interference, and space debris, the American Astronomical Society's Committee for the Protection of Astronomy and the Space Environment (COMPASSE) has experienced a significant burst of growth and activity in the last five years. Its vision is a Society whose members constitute a visible presence and an effective voice in the effort to protect dark and quiet skies and the integrity of the space environment for the future of astronomy and for humanity. COMPASSE members are working hard to educate astronomers, industry leaders, elected officials, and the public about the critical importance of protecting the sky for astronomy, human health and cultural heritage, and the environment, and to defend space as part of that environment. This presentation will summarize those activities and plans for the near future. We are active in promoting sensible regulation at the local, state, national, and UN levels. We have briefed federal agencies and offices from the White House to Congress to the Departments of State, Commerce and Defense. We have developed outreach and educational programs and materials. We collaborate with an ever-broader circle of partners with mutual interests in preserving dark and quiet skies, and we aim to forge closer connections and build effective partnerships with our international friends and colleagues through the IAU. The sky urgently needs our help, and we are eager to work with the growing global movement to protect it.

Preserving Dark Skies: The Hanle Dark Sky Reserve Initiative

Mr Dorje Angchuk[1], Prof Niruj Ramanujam[2], Mr. Stanzin Norlha[3], Mr Nawang Dorji[4], Mr Sonam Jorphail[2], Mr. Tsewang Gyalson[2], Mr. Tsewang Stanzin[2], Prof Annapurni Subramaniam[2]

[1]Indian Institute of Astrophysics. [2]Indian Institute of Astrophysics, India. [3]Bhabha Atomic Research Center, India. [4]Tata Institute of Fundamental Reserch, India

Abstract

The exceptional quality of night sky attracted the creation of the Indian Astronomical Observatory in Hanle around two decades ago. The rise of traditional tourism and local development activities contributed to an increase in light pollution. In response to this challenges, Hanle Dark Sky Reserve(HDSR) was conceived as a sustainable model to conserve the pristine night sky while also leveraging it to benefit local communities. The uniqueness of HDSR is that it operates through a collaborative framework involving professional astronomer, local communities, and strong government support.

Central to HDSR's strategy is the implementation of a Light Management Plan (providing warm bulbs, lamp shades and curtains to all the household). The local government is also investing in astro-tourism infrastructure including mini planetarium, transparent domes and entry gates to guide visitors.

Community engagement is emphasized to foster a sense of ownership of the night sky, with local villagers being provided and trained as Astronomy Ambassadors to showcase the night sky's beauty to the tourist.

We are also constantly monitoring light pollution levels with SQM and DSLR camera to access the impact of artificial light. Annual star parties at HDSR foster interaction between Astronomy Ambassadors and amateur astronomer raising awareness about dark sky conservation.

Overall HDSR is an innovative campaign raising public awareness nationwide about designated dark skies areas, sky watching and importance of preserving dark skies for ecological, cultural and scientific reasons. It has spurred the development of astro-tourism, guided tours, and immersive experiences of night sky.

Progress in Citizen Science through the Globe at Night and the Glowatch in combatting Light Pollution

PhD Daniela Gonzalez[1], PhD Constance Walker[2,3]

[1]Skies of Chile Foundation. [2]NSF NOIRLab. [3]IAU CPS

Abstract

Citizen science initiatives have emerged as indispensable tools in the current academic discourse around light pollution mitigation, exemplified by the 18-year-old Globe at Night project. Globe at Night is an international citizen science campaign involving citizen scientists who measure and submit observations of night sky brightness. This helps to create a global map of light pollution, highlighting the proliferation of this problem, and underlining the need for innovative prevention and mitigation strategies.

In response to this demand, Glowatch emerges as a citizen science platform that enables citizens to systematically identify and document sources of light pollution. The involvement of diverse communities not only reinforces specific control measures, but also advocates for improved outdoor lighting practices, especially relevant in astronomical regions such as Chile, crucial for scientific observation.

The effectiveness of citizen science tools such as Globe at Night and Glowatch depends on accessibility across all demographic spectrums. To ensure participation rates and maintain the integrity of the data collected, efforts must prioritize inclusion and address digital barriers, facilitating scientific engagement and amplifying the impact of data acquisition.

By building on initiatives such as Globe at Night and Glowatch, the academic community deepens the global understanding of light pollution and its implications. Increased awareness, particularly in dark sky preservation regions, underscores the need for collaborative action. Collectively, our goal remains to mitigate the effects of light pollution, thereby safeguarding dark skies for posterity and strengthening a shared commitment to the preservation of this heritage.

Innovative Strategies for Astronomical Conservation: A Dark Sky Preservation Initiative in Kenya

Miss Carol Nyaguthii

DarkSky Kenya

Abstract

The Kenyan Chapter of DarkSky focuses on the preservation of natural darkness in the Kenyan context, with an approach combining community engagement and policy advocacy. Initiating the plan, community involvement through citizen science for light pollution mapping aims to cultivate awareness at the grassroots level. Concurrently, International Dark Sky Places designations, mapping of the region for light pollution measurements, and advocacy for robust policies underscore our commitment to aligning conservation efforts with sustainability, development goals, and human well-being.

Furthermore, by integrating light pollution measurements into our comprehensive approach, we not only address the immediate concerns of community engagement and policy advocacy but also contribute valuable data for the identification of ideal locations for astronomical observations.

A central component of our strategy involves pioneering pilot projects in outdoor lighting evaluation. The subsequent presentation of these projects, along with proposed corrective measures, to local authorities aims to establish a foundation for a sustainable implementation plan. Our focus on collaboration with lighting professionals, urban developers, and urban planners positions this initiative as a model for integrating conservation with urban development in a balanced manner.

As the first DarkSky Chapter in the region, our collaborative efforts with the Kenya Wildlife Conservation Association signify a leadership role in advocating for dark sky preservation. Furthermore, fostering a dialogue on sustainable practices aims to preserve natural darkness as a desirable outcome not only for the astronomy community but for the well-being of the entire ecosystem.

Impact of light-pollution on the quality of San Juan skies: Towards a Law to protect and preserve the sky in San Juan, Argentina

Lic. Claudia Alamo, Nelson Ariel Rodríguez, Dr. Sergio Cellone

Complejo Astronómico El Leoncito (CASLEO), Argentina

Abstract

The goal of this project is the elaboration of a light-pollution atlas through a photographic (Sky Quality Camera, "SQC") and photometric (Sky Quality Meter, "SQM") survey in strategic areas around the professional and science outreach observatories. This will be the basis for the upgrade of the Provincial Law 5771 (sky protection), The present project is a collaboration between the El Leoncito Astronomical Complex (CASLEO, CONICET - UNLP - UNC - UNSJ), the Félix Aguilar Astronomical Observatory (OAFA, UNSJ), The Dr. Carlos Ulrrico Cesco Astronomical Station, and the Secretaries of Environment and of Science & Technology of San Juan province. Joanma Bullon (President of AstroARAs - Valencia, Spain) is the technical advisor of this project.

We present results from the initial stage of this project, consisting of the first images obtained with a camera Canon 6D Mark II equipped with a Canon Fisheye 18-55 mm lens (SQC), which span 180 degrees of the sky in the strategically selected sites.

The second instrument, an SQM, will be acquired at a second stage; it will allow us to perform quantitative measurements of the sky brightness.

In order to carry on this project, we gathered an interdisciplinary team (astronomers, technicians, outreach staff) which is working with a short, medium, and long-term planning to evaluate the evolution of light-pollution affecting the San Juan province sky.

Stargazing from the Himalayas: NASO's Efforts in Fostering Astro-Tourism in Koshi Province of Nepal

Mr. Oshan Sharma Kattel, Ms. Manisha Dwa, Mr. Suresh Bhattarai

Nepal Astronomical Society

Abstract

Nepal boasts significant potential in astronomy, marked by its dark skies and low light pollution. For over a decade, Nepal Astronomical Society (NASO) has been playing a pivotal role in advancing the nation's astronomical landscape, concentrating on outreach, education, and research. Amidst Nepal's already thriving natural tourism industry, the minimally polluted night skies have consistently been recognized as an additional asset for the country's tourism sector.

With its continuous efforts to raise awareness about light pollution and its adverse effect on night skies, NASO has been working with ministries and local governments of Koshi Province to conduct the feasibility study of Astro-Tourism in different areas of Solukhumbu (home to Mt. Everest) and Illam districts with a motive to conserve the dark skies and establish them as the Astro-Villages. Capitalizing on the well-established tourism infrastructure, NASO aims to develop Astro-Tourism not only to safeguard dark skies but also to create employment opportunities within these communities by introducing Astro-Tourguides and promoting homestays. This paper will delve into NASO's initiatives, focusing on the collaborative efforts involving various levels of government, tourism industry, and local communities to protect night sky darkness and promote Astro-Tourism with sustainable and community-driven efforts in the Solukhumbu and Illam districts of the Koshi Province of Nepal.

Stewardship of the Environment and Heritage of the Skiesfor Science and Humanity

Mr. Ruskin Hartley[1], Dr. Aparna Venkatesan[2]

[1]DarkSky International. [2]University of San Francisco

Abstract

In the past year, DarkSky International has spearheaded an effort, gathering a diverse, multi-disciplinary group from nine countries to establish a coalition to preserve the night sky. This initiative emphasizes the urgent need to collaborate with a broad spectrum of constituencies beyond the astronomy community to address the challenges of light pollution and satellite proliferation, which pose significant threats to human health and ecosystems, wildlife, and the natural beauty of the night sky.

The coalition's strategy centers on building a global alliance that not only involves astronomers but also engages environmentalists, policymakers, Indigenous communities, and the general public. This collaborative approach aims to create a shared commitment to the night sky as our common ancestral heritage, connecting dark sky preservation with broader concerns such as sustainable economic development, storytelling and sky traditions, advocacy and education, and equity/inclusion.

Our coalition is launching a global campaign that aims to mitigate the adverse effects of artificial light at night (ALAN) and promote responsible satellite deployment. The goals include reversing ALAN's expansion, reducing its environmental and societal impacts, and fostering equitable access to the night sky. By uniting diverse perspectives in a concerted effort, the initiative strives to amplify its message and secure meaningful, lasting achievements. This collective action aims to protect our night skies for future generations, ensuring the cosmos's wonders remain accessible to all, marking a significant step towards a brighter (yet darker) future.

The Mauritius Radio Telescope (MRT) site: need for preservation as an Astronomical Observatory for both Radio and Optical observations.

Associate Professor (Dr) Nalini Heeralall-Issur

University of Mauritius

Abstract

The Mauritius Radio Telescope (MRT) site is situated on state land, within the Bras-D' Eau forest, in the small (1865 sq km) island of Mauritius. MRT was an Indo-Mauritian venture, developed in the 1990s, to survey the Southern Radio Sky at 150 MHz. This 2 km by 1 km T-array of helical antennas, was also equipped with a pulsar observing capability.

Although MRT is now decommissioned, the infrastructure developed at the site makes it ideally situated for astronomical observations, within the densely populated (1.3 M inhabitants) island of Mauritius. It has a good road access, an observatory building, electricity, telephone lines and internet connectivity, but with no densely inhabited areas and city lights in close proximity, RFI levels remain relatively low and one can enjoy relatively dark skies.

The site has known a general degradation over the years, mainly due to a lack of funds for hiring appropriate staff. Nevertheless, various new installations and prototypes for radio observations have been set-up, in preparation for our involvement as a partner country with South Africa for the SKA project. Occasionally open nights are held for night-sky viewing. More recently, DARA funded international research students have set-up an array of small parabolic antennas for radio observations at 1420 MHz.

However, in such a densely populated small island, explicit measures must be taken to safeguard the site so that it remains suitable for both radio and optical astronomical observations. We discuss possible avenues to ensure this in a sustainable manner.

Investigating the Influence of Dark Sky Assessments on Environmental Strategies in 4WD Expeditions and the Development of Astro Tourism in Iran's Desert Wilderness

Mohammad Saleh Timar

Nojum Magazine

Abstract

Last Autumn, we have measured the darkness of the night sky at more than 20 locations deep within the deserts of Iran using SQM. These measurements were conducted in remote areas accessible only by specialized 4WD expeditions. The purpose of these adventurous trips was not just for measuring the darkness. They were part of a program, which helped us with budget management of our darkness measurement project and the development of astro tourism under the darkest skies of Iran's desert belt. We conducted desert expeditions, combined with astro tours in remote desert areas. This approach helped us to promote astro tourism to the Desert tourism community, who conduct adventurous 4WD tours, and creating a new trend in this sector of tourism. This combination, also provided our fellow travelers with the opportunity of learning about astronomy and observe the night sky during their free time at night. Many of these tours previously neglected the night sky due to bright lights at camp; now, participants can better appreciate the beauty of starry sky. Furthermore, these combined adventure and astro tours, familiarize participants, often politically influential, with the significance of dark skies. This is crucial as many political figures in Iran are unaware of the importance of dark skies. Additionally, by shifting camp lighting from white and to yellow, these tours reduce light pollution, benefiting desert dwellers who are less affected by the glare of artificial lights. In this presentation, I will discuss the other positive and impactful aspects of this project.

Good Night Collective - interdisciplinary efforts to protect the dark skies in Poland

Justyna M. Olszewska[1], Przemysław J. Mikołajczyk[2,3], Dr. Karolina Dziadura[1], Michał Pawłowski[1], Krzysztof Kotysz[2], Dr. Sylwester Kołomański[2]

[1]Astronomical Observatory Institute, Faculty of Physics, A. Mickiewicz University, ul. Słoneczna 36, 60-286 Poznań, Poland. [2]Astronomical Institute, University of Wroclaw, ul. M. Kopernika 11, 51-622 Wrocław, Poland. [3]Astronomical Observatory, University of Warsaw, Al. Ujazdowskie 4, 00-478 Warsaw, Poland

Abstract

Good Night, an interdisciplinary collective, merges astronomy and fine arts to bridge the gap between science and society. Comprising graduates in astronomy and photography, our collective emphasizes visual science communication. Our initiatives include exhibitions, workshops, and a popular science radio broadcast. Through Project Aurora Nord, we researched the aurora borealis and partnered with SOLAR, a clothing company, to create a collection featuring aurora patterns and an educational campaign on preserving dark skies. Our exhibitions, held in prestigious art and education institutions across Poland, aim to raise awareness about light pollution. Educational workshops during events like the Night of Museums and art festivals complement these exhibitions, deepening understanding of astronomical concepts and environmental issues. Our popular science radio program broadcasts astronomy content and discusses light pollution, reaching a broader audience. Good Night is committed to helping small communities combat light pollution directly. We collaborate with local initiatives, providing support and resources to reduce artificial light at night, leading to noticeable improvements in light pollution levels. The culmination of our activities is cooperation with ALPS (All-sky Light Pollution Survey). ALPS is designed to monitor light pollution by recording images and measuring the brightness of the night sky. These observations are made using automated measurement stations. We have secured funding to build two such stations in strategic locations in our hometown of Poznań, Poland: Astronomical Observatory in Chalin (Dark Sky Reserve area, Poland), outskirts of Poznań near the Morasko Nature Reserve. https://www.instagram.com/goodnight_collective/

Title : Detecting Faint Radio Frequency Interference (RFI) in MeerKLASS Single Dish data

Ms Tamera Kassie

SARAO/ University of Western Cape

Abstract

MeerKLASS is a single dish HI intensity mapping survey of the MeerKAT Telescope. Probing the 21 cm signal is coupled with challenges from foregrounds and radio frequency interferences (RFI) which contaminates the data, and in turn our cosmological signal. The MeerKLASS collaboration was already able to produce a detection of the HI cosmological signal using cross-correlations with galaxy

surveys (Cunnington et al, Monthly Notices of the Royal Astronomical Society, Volume 518,

Issue 4, February 2023, Pages 6262–6272). However low-lying RFI still remains, in this talk I will be discussing the cleaning methods that I will be applying to the MeerKLASS data to remove faint RFI signatures, by removing these low lying RFI we expect to have reduced data lost due to aggressive flagging of RFI contaminates across channels to increase our S/N for an improved detection of the 21 cm signal.

[1]Associated Universities Inc.. [2]International Astronomical Union Office for Astronomy Outreach (OAO). [3]University of Portsmouth. [4]Logos Evaluation. [5]International Astronomical Union Office of Astronomy for Education (OAE). [6]Florida State University. [7]National Science Foundation

Abstract

Since the dawn of our existence, the night sky has captured our imagination and inspired humans across the globe. Today, astronomy is seen by many as a gateway to inspiring interest and learning in students and the general public and has demonstrated its ability to engage people across cultures and political borders. ASTRO ACCEL is a new initiative working to build an international network of networks (NoN) to accelerate research and research to practice in astronomy education, engagement (outreach), communications and culture. The 3-year project initially engaged 13 networks across 6 continents of our globe to explore and develop tools and techniques and build the human infrastructure necessary for a vibrant and sustainable NoN. We now seek to engage additional research and practitioner network partner institutions and individuals, including for our newly-establish Early Career Researcher (ECR) Network. This presentation will provide an overview of the project's current status, short and long-term plans, how you can get involved, and participate in the growing Early Career Researcher (ECR) network that is part of ASTRO ACCEL. ASTRO ACCEL is funded by the U.S. National Science Foundation's Office of International Science & Engineering.

Unlocking Inclusive Outreach: Connecting Minds to Science

Dr Nadeem Oozeer

South African Radio Astronomy Observatory, 2 Fir Street, Black River Park, Observatory, Cape Town 7925, South Africa. Department of Physics and Electronics, Rhodes University, PO Box 94, Grahamstown, 6140, South Africa

Abstract

The importance of outreach for organizations, particularly for emerging projects like the Square Kilometre Array (SKA), cannot be overstated. However, our current outreach methods often overlook neuro-diverse populations. True outreach aims to engage diverse minds in scientific thinking rather than promoting specific career paths. Building long-term relationships with our audience is crucial for success, fostering an understanding of how our world and universe interact. Despite the diversity within humanity, many outreach efforts fail to incorporate this diversity such as those with; visual and hearing impairment, and differently abled people. We tend to work with diverse groups individually instead as a collective body. While traditional systems target specific groups like primary and secondary schools, and the general public, even these groups can contain diverse individuals, such as those with visual impairments. In this presentation, I will discuss the importance, methods of inclusive outreach and how we can connect minds to science.

OAE, OAD, OAO Roundtable

Dr Tshiamiso Makwela[1], Dr Markus Pössel[1], Kevin Govender[2], Dr Joyful Mdhluli[2], Kelly Blumenthal[3], Camilo Delgado-Correal[4,5]

[1]IAU Office of Astronomy for Education. [2]IAU Office of Astronomy for Development. [3]IAU Office for Astronomy Outreach. [4]Francisco José de Caldas District University of Bogotá & IGAC. [5]IAU National Outreach Coordinator Colombia

Abstract

The International Astronomical Union (IAU) is the largest international association of professional astronomers, with over 12000 individual members representing more than 85 countries. More than just a centrepiece for academic research in astronomy, the IAU hosts Offices and Centres that carry out its mission and vision. In this panel, we will hear from representatives of three of the IAU Offices: the Office of Astronomy for Education (OAE), the Office of Astronomy for Development (OAD) and the Office of Astronomy Outreach (OAO). These Offices work synchronously, recognising the important overlap between their focus areas through the work of the OAE National Astronomy Education Coordinators (NAEC), OAE Nodes and OAE Centers, Regional and Language Offices of Astronomy for Development (ROADs and LOADs) and the IAU OAO National Outreach Coordinators (NOCs). Through the IAU's vibrant and diverse network of networks, the Offices work together to promote the uptake of astronomy in schools, empower learners of all ages with critical thinking, and leverage the power of astronomy to inspire people to imagine a different – or another – world. During this session, representatives of these Offices will discuss their joint and individual efforts, their hopes for the future of their networks, and how the Junior Members can get involved.

Exploring Astronomy as a Tool for Enhancing Mental Health

Dominic Vertue, Joyful Mdhluli, Mampho Ledimo

IAU Office of Astronomy for Development

Abstract

“Astronomy for Mental Health'' is a flagship project of the International Astronomical Union’s Office of Astronomy for Development (IAU-OAD). The project is focused on harnessing the inspirational potential of astronomy and using it as a tool for improving people’s mental health and wellbeing. The overarching goal is to use astronomy to empower individuals and communities to reach their full potential. In 2023, pilot projects targeted undergraduate and postgraduate students, addressing common stressors identified through pre-launch surveys. The Mental Health team developed resources to guide participants on how they can utilize astronomy as a tool for managing daily challenges. Some of the pilot projects that were hosted include a writing retreat, which was hosted in a remote area for MSc and PhD students to explore whether dark sky areas could enhance concentration and inspire productivity in the process of completing their work. In addition, online workshops were conducted, tailored for physics students, and sessions were dedicated to exploring the potential of Astronomy as a tool for enhancing mental well-being. This presentation will showcase the pilot activities, including key takeaways and implementation strategies for broader applications.

Addressing Gender Disparities in Astronomy: A Comprehensive Review of Challenges and Opportunities faced by Women Researchers.

Dr. Mamta Pommier

University Catholic of Lyon, University of Lyon FRance

Abstract

Persistent systemic inequalities are observed for women in Astronomy and STEM fields throughout their professional journeys. Effectively addressing these challenges requires a proactive approach focused on raising awareness, supported by comprehensive statistical data. This approach is crucial for closely monitoring career hurdles and addressing underlying barriers to workplace equality, contributing significantly to rectifying the leaky pipeline effect and gender imbalances in STEM careers. In this talk, I will present the efforts carried out by the IAU WiA WG to advance inclusivity and equal opportunities in Astronomy.

Women in Astronomy: A Comprehensive Situational Analysis in Zambia

Dr. Jive Lubbungu

Kwame Nkrumah University, Zambia

Abstract

This study presents a thorough situational analysis of the status, obstacles, and opportunities for women in the field of astronomy in Zambia. Despite the global advocacy for gender inclusivity in science, technology, engineering, and mathematics (STEM) disciplines, the involvement of women in astronomy remains inadequately examined, particularly in the context of developing nations such as Zambia. Employing a qualitative methodology, this research gathers data on the current demographic landscape of women in astronomy in Zambia, with qualitative insights derived from in-depth interviews with key informants purposively selected through snowball sampling techniques. The findings illuminate the various barriers confronting women aspiring to enter and excel in the field of astronomy, spanning from cultural perceptions to systemic challenges within educational and professional realms. Furthermore, the investigation reveals a gender bias favoring men in the field of Astronomy within Zambia, with only one woman identified, who is not even residing in the country. By unraveling the distinctive challenges faced by women in this discipline, the research seeks to provide valuable insights for crafting targeted interventions and policies, fostering a more inclusive and equitable environment that encourages women to pursue successful careers in astronomy.

The Supernova Foundation: A mentoring and networking programme for women in physics

Dr Michelle Lochner

University of the Western Cape. South African Radio Astronomy Observatory

Abstract

The Supernova Foundation (www.supernovafoundation.org) is a global mentoring and networking programme aimed at women and gender minority physics students, mostly from developing countries, to try to improve gender equality in physics. We target women in physics departments with few or no woman role models and use mentoring by senior female researchers to empower them and give them the support they need to stay in physics. We currently have nearly 400 mentors and mentees from six continents. We regularly host webinars on topics like imposter syndrome or work life balance and our mentors meet their mentees monthly for private sessions. As founder and director, I will overview the Supernova Foundation in this talk, lessons learned and tips for successful mentoring programmes.

Women and Girls in Astronomy Program (WGAP)

Sr. STEM Education Specialist Yasmin Catricheo[1], NA-ROAD / WGAP Coordinator Karla Garcia[2], AURA Corporate Communications Coordinator Shari Lifson[3], Staff Associate for Facilities Planning and Management Tim Spuck[4], VP of Science Engagement Laura Trouille[5]

[1]Associated Universities Inc. (AUI). [2]North American Regional Office of Astronomy for Development (NA-ROAD). [3]Association of Universities for Research in Astronomy (AURA). [4]U.S. National Science Foundation. [5]Adler Planetarium / Zooniverse

Abstract

The Women and Girls in Astronomy Project (WGAP) is a key project of the North American Regional Office of Astronomy for Development (NA-ROAD). WGAP inspires and supports women, girls, and underrepresented genders in the field of astronomy. The program targets aspiring astronomers and current professionals alike to establish a network to uplift, educate, connect with, and promote astronomy for development in women and girls located in communities from the North American Region which includes the United States and U.S. Territories, Canada, Mexico, Greenland, and several island nations of the Caribbean.

This year, ten chosen projects were awarded with $2,000 USD mini-grants and project leaders will join the WGAP network as WGAP Fellows. This network is composed of industry and academic professionals who are willing to support women and girls in astronomy, while facilitating connections between women and girls in astronomy. Proposals answered four key questions specifying the following details regarding the proposed project; clear vision and goals for the project; clear target audience; how the project plans to support the target audience; timeline aligned with a December 1, 2024 completion date, and, an organized budget, with projected expenses for materials and/or travel. After this second consecutive year, WGAP has been able to support a total of 20 projects that target specific communities across the North American region. Throughout the presentation, we will learn more about the WGAP projects and their impact on local communities across the North American Region. Thanks to the Heising-Simons Foundation for supporting the WGAP program.

Gender balance at CBK PAN after implementing the gender equality plan.

prof Jolanta Nastula

Centrum Badań Kosmicznych PAN

Abstract

The Centrum Badań Kosmicznych PAN (CBK PAN), or the Center for Space Research of the Polish Academy of Sciences, stands as one of the leading centers in Poland for space research. The institute is committed to creating a workplace that offers its employees favorable working conditions and opportunities for scientific development.

Throughout the 45-year history of the Centrum, the number of female employees has shown consistent, albeit gradual, growth. In 2015, women constituted approximately 34% of the total workforce, and by the end of 2020, this figure had increased to over 37%. In 2022, CBK PAN introduced a gender equality improvement plan. This presentation outlines the current situation.

The Role of Women in Astronomical Observation and Astrophotography in Iraq- Challenges and Aspirations

Mrs Najah Al-Salihy

Arab Union for Astronomy and Space Science

Abstract

In Iraq, women and girls who with interest in astronomy, face tremendous challenges that often intersect with broader societal barriers. One significant hurdle is the lack of inclusive spaces and opportunities for participation. Amateur astronomy clubs and events may be predominantly male dominated and creating an environment that feels unwelcoming or intimidating for women and girls. Specially taking in account that most astronomy observations and astrophotography events take place overnight and in areas away from the center. Cultural norms and societal expectations make it difficult for aspiring female astronomers to participate in such events and connect with likeminded peers and mentors.

Additionally, the financial challenges and access to equipment and resources is limited and particularly in regions with socioeconomic disparities and areas of conflict, like Iraq. High quality telescopes and other astronomical instruments can be expensive and difficult to obtain and placing them out of reach for many amateur enthusiasts and especially women and girls from marginalized communities.

Moreover and societal stereotypes and gender biases may lead to the underestimation of women's abilities in technical fields like astronomy and further exacerbating the challenges they face in pursuing their interests and gaining recognition for their contributions.

In conclusion, there is a significant lack of representation of women in the field of astronomy in Iraq, the way forward is to support women in new initiatives and increase awareness in the society advocating for gender equality and striving to overcome barriers to pursue their passion for astronomy and astrophotography.

Advancing Diversity and Inclusion in Indian Astronomy and STEM for Women and Minority.

Miss Sarah Ann Jacob

International Space University

Abstract

In recent years, India has celebrated remarkable achievements in space exploration, yet beneath the surface lies a stark reality of underrepresentation within its astronomy and STEM sectors. This study endeavors to illuminate the challenges faced by women and minorities in these fields, identify underlying mechanisms contributing to their underrepresentation, and propose actionable solutions for fostering diversity and inclusion.

Through a comprehensive approach encompassing literature reviews, interviews, and survey analysis, this research seeks to uncover the nuanced factors driving the underrepresentation phenomenon. The concerning trend of significant proportion of women and minorities exit the STEM sector post-graduation, perpetuating the disparity in representation., disparities in pay scales, inadequate mental health support, and a lack of mentors and training exacerbate the challenges faced by marginalized groups.

The urgency of action is evident, and this study serves as a call to create a more inclusive and equitable environment within Indian astronomy and STEM fields. By providing a platform for marginalized voices to be heard, the research aims to shed light on experiences and concerns that have long been overlooked and highlighting the necessity of amplifying these voices and fostering collective action to address systemic barriers to pave the way for a more inclusive future in Indian astronomy and STEM for women in India and globally , where every voice is valued and respected.

This abstract encapsulates the the potential impact on promoting diversity and inclusion in Indian astronomy and STEM fields , this study seeks to effect transformative change within India's scientific landscape.

ICRAR Visiting Fellowship For Senior Women+ In Astronomy

Dr Renu Sharma, Ms Asha Stabback, Prof Luca Cortese, Dr Elisabete DaCunha

University of Western Australia - ICRAR

Abstract

ICRAR (International Centre for Radio Astronomy Research), based in Perth, Western Australia established a Fellowship scheme in 2014 providing a full-funded Visiting Fellowship for Senior Women+ in astronomical sciences and technology. The purpose is to enable an opportunity for senior women+ astronomers, as well as engineers and data scientists working in the field of astronomy, (having more than five years research work experience post PhD) to visit ICRAR and interact with ICRAR researchers and graduate students.

Through the Fellowship scheme, opportunities are created for the Visiting Fellow to share their experiences and challenges as they progress in their career, foster scientific interaction and enrich the research environment through National and International collaborations, mentor and support students and early-career researchers.

Since its establishment, ICRAR has supported seven (7) Fellowships, with travel restrictions during Covid impacting full Fellowships being awarded but an additional two (2) senior researchers were supported to visit ICRAR.

In this talk, we will outline the program, challenges faced, learnings along the way as well as the future of the program. We will also highlight the outcomes of the program and how this initiative has supported our broader diversity, equity and inclusion initiatives and contributed to recognition at a national level with the Gold Pleaides award. The Pleiades Awards, inspired by the UK's Athena SWAN program, were originally launched by the ASA Chapter for Women in Astronomy (WiA) to recognise organisations in Australian astronomy that take active steps to advance the careers of women.

MUJERES POR AFRICA": a case study of research and collaboration opportunities for women in astronomy

Dr Brenda Namumba[1], Dr Elizabeth Naluminsa[2], Dr Pfesesani Van Zyl[3]

[1]The University of Witswatersrand. [2]Makerere University. [3]South African Radio Astronomy Observatory, HartRAO site

Abstract

Dedicated to helping Africa's development through the empowerment of its women, the Women for Africa Foundation (FMxA) aims to promote leadership among African women in scientific research and technology transfer, as well as strengthen the capabilities of research centres in their respective countries. Our talk will explore the amazing research collaboration opportunities available to African women in astronomy through the Mujeres por Africa fellowship while showcasing the stories of both previous and current recipients. By fostering partnerships between Africa and Spain, these efforts have further strengthened collaborations between astrophysical research institutions across Africa and the IAC, facilitating access to data from international facilities such as the ING and MAGIC telescopes. This collective effort significantly contributes to shaping the future of astronomy in Africa, simultaneously amplifying the voices and acknowledging the achievements of women in their respective fields.

Work and achievements of the African Network of Women in Astronomy

Dr. Mirjana Povic[1], Dr. Vanessa McBride[2], Dr. Somaya Saad[3], Dr. Priscilla Muheki[4], Ms. Salma Silla Mbaye[5]

[1]Space Science and Geospatial Institute, Ethiopia. [2]IRC, France. [3]NRIAG, Egypt. [4]MUST, Uganda. [5]Universidad Cheikh Anta Diop, Senegal

Abstract

The African Network of Women in Astronomy (AfNWA) is an initiative that aims to connect women (or people who identify as such) working in astronomy and related fields in Africa. It was established in September 2020 as one of the committees of the African Astronomical Society (AfAS). With AfNWA we want to ensure the future participation of girls and women at all levels in the development of astronomy and science in Africa. Our main goals are to improve the status of women in science in Africa and to use astronomy to empower girls and women, and to inspire more girls to pursue Science, Technology, Engineering and Mathematics (STEM). This talk will summarise the activities carried out by AfNWA and the current status of women in astronomy in Africa. It aims to give visibility to the work and achievements of the AfNWA community, and the various activities carried out across the continent to support girls and women living and working in under-represented communities through astronomy. He will also emphasise our vision of how through astronomy we can combat poverty in the long term, and increase our chances of achieving the UN Sustainable Development Goals (SDGs) in the future, including SDG 5 related to gender inequality, for the benefit of our society as a whole. The last part of the talk will cover a list of AfNWA's recommendations to improve the strong gender gap we still have in science around the world.

Rise of Women in Astronomy in Nepal: a Lilac revolution

Ms. Manisha Dwa[1,2,3,4], Mr. Suresh Bhattarai[1,5,3,4]

[1]Nepal Astronomical Society. [2]IAU-Office of Astronomy Outreach. [3]IAU-Office of Astronomy for Education. [4]OAE-Node Nepal. [5]IAU Office for Astronomy Outreach

Abstract

Due to various reasons including traditional standpoints, socio economic aspects, societal hegemony, the number of female students pursuing STEM field is very low in Nepal. In this scenario, trying to find the female astronomer is near to zero. I as an individual, when developed the interest in astronomy and tried astrophotography, I was victimized by the stereotyped comments which were extremely discouraging. Despite the challenges, I gather the courage and have a very limited people supporting me, leading to be the person I am.

It has almost been a decade I started working in the field of Astronomy and today, we have handful of female professionals and students who are contributing to the field and are inspiring their local communities to pursue STEM field. This paper thus will share about the contribution of few of the female leaders who have been involved in astronomy outreach throughout Nepal. The paper will mainly focus on the outreach and educational activities they are involved in and the visible change through the records/data thus collected by them. Particularly, this paper will discuss about the Teachers Training Program (TTP) conducted under International Astronomical Union -Office of Astronomy for Education (IAU-OAE), project ACEN (an IAU-OAD initiative) and the various astronomy outreach sessions during the World Space Week celebration by the female participants throughout the country. As we are open to welcoming everyone under this category who bears the pronoun she/her, the theme of this work will be the Lilac revolution.

The Astronomoms survey - how to better support parents in astronomy

Dr Veronica Allen[1], Dr Melinda Soares-Furtado[2], Prof Jessica Degol[3]

[1]University of Groningen. [2]University of Wisconsin, Madison. [3]Pennsylvania State University

Abstract

In 2020, amid COVID19 lockdowns, uncertainty, and extreme work/life imbalance, two early career moms in astronomy started an online coffee morning chat. Neither fully relating to academic non-parents or non-academic parents, we needed a space to create a community where we could share advice and support; so **Astronomoms** was born.

Since then, we have grown to more than 40 members, hosted a dozen talks from mentor Astronomoms, and started down the path of systemic change. In this vein, Melinda Soares-Furtado (*UWisc Madison*) and I, together with Jessica Degol (*PSU Prof of Human Development and Family Studies*) conducted a survey of parents in astronomy. In this talk, I will present the results of this survey as well as our suggested institutional actions to better support caregivers.

PROVOCA mentorship program

Dr. Sonia Duffau

Associated Universities, Inc. (AUI) & National Radio Astronomy Observatory (NRAO)

Abstract

Women continue to be under-represented in Astronomy and STEM in general. The PROVOCA initiative has been building a safe space for female STEM professionals, girls and young women to meet since 2018. Initially, as one-time opportunities and later on as a year-long mentorship program focused on increasing knowledge of STEM disciplines, developing key skills and building a support network. The mentorship program hones communication and teamwork skills, exposes students to the reality of everyday life as a female in STEM and creates opportunities to connect. The overall objective is to generate a strong sense of belonging and STEM identity, addressing the issues of participation, retention and representation of women in Astronomy and STEM.

PROVOCA trains its own female in STEM mentors, 50% of which come from Astronomy. In a thorough 8-month experience, volunteers prepare to accompany and guide high school and early college students.

A metric of success for the mentor training is to arrive at a better understanding of their career paths, extracting lessons to share with students. For the students, a successful process is one where they were able to explore career options to make thoughtful and informed decisions.

Since the beginning of the mentorship program in 2021, 51 mentors have been trained and 88 students have participated, including 2 students from the deaf community. 100% of the mentors who were selected, finished their training, with almost 90% retention rate for the students.

We will show how PROVOCA helps solidify STEM identity for the girls and women involved.

Women in the skies

Dr Ana Cecilia Soja

Fluminense Federal Institute

Abstract

Since its beginning, Humanity has projected its stories in the skies. Each civilization at its proper historical moment imprints values and culture in the stars. Just over a hundred years ago, the current constellations of the Western world were defined, based on the Hellenic tradition. The result was 88 constellations, most of which tell the stories of warriors and heroes. Among them, only six constellations tell women's stories. The present work goal is to analyze these stories. In this way, first we characterized such narratives in order to understand the model of femininity that is being celebrated and its impact on the collective imagination. Then, a comparison was made between this pattern and the one adopted for male figures. It was found that, while for idealized male figures the highlighted qualities were courage and strength, female figures are usually depicted as secondary characters in an hero's life and their biggest quality comes out as beauty. As expected, these stories reinforce Western society's gender stereotypes. Having made this observation, the next step was to think of suggestions on how to use Astronomy and observation of the sky as an auxiliary tool in the search for gender equality. Thus, it is concluded that a possible strategy is to tell the stories of these women in the skies, emphasizing their agency in their own adventures and highlighting qualities beyond their beauty or being male characters' objects of desire.

Women in Physics: Inclusion for all

Dr Katekani Shingange[1], Dr Joyful Mdhluli[2]

[1]Mintek. [2]Office of Astronomy for Development

Abstract

Despite notable advancements in recent years, women continue to confront underrepresentation in physics and astronomy, encountering unique barriers that hinder their complete engagement and progression within the field. Women in Physics in South Africa (WiPiSA), a dedicated forum under the South African Institute of Physics (SAIP), is committed to championing the cause of women in these intertwined disciplines and advocating for increased female participation in physics and astronomy-related careers.

Addressing the imperative question of how to attract and retain females in these fields remains a formidable challenge. Proposed initiatives encompass the amplification of diverse voices and shared experiences, highlighting the importance of identifying and celebrating perspectives beyond gender. Additionally, building supportive communities is highlighted as crucial, exploring the key role of community-building in establishing networks that prioritize mentorship, advocacy, and collaborative environments conducive to mutual growth.

WiPiSA engages in various activities aimed at attracting and retaining females in Physics-related careers, including science outreaches, Physics departmental lunches, webinars, mentorship, and role modelling. Through these activities, it can be realized that intersectionality in action calls for exploration of approaches to inclusion that recognize and address the interconnected nature of various identities, ensuring a subtle understanding of the challenges faced by different groups within the physics and astronomy communities. This work aims at sharing the WiPiSA engagements, share the successful stories and challenges faced at attracting and retaining females in Physics.

Culturally-Relevant Role Models for Girls in South Asia

Ms. Yumna Majeed

Exploration - Cosmos to Classroom

Abstract

Addressing the persistent challenge of the underrepresentation of women in long and fulfilling STEM careers despite an increase in their enrollment in South Asian countries. Cultural barriers, societal norms, and gender-specific expectations, such as marriage and domestic responsibilities, hinder women's progression in STEM fields. The proposed solution focuses on empowering teachers, the nation builders, by providing training and resources to engage girls in STEM and Space-related disciplines. Acknowledging the scarcity of qualified teachers in South Asia, the research advocates for international fellowships and scholarships, culturally relevant STEM experiences, and strategic plans to counteract the masculinization of certain fields.

The paper emphasizes the importance of women-led STEM initiatives in Pakistan, India, Nepal, and Bangladesh, where female educators serve as crucial role models for young girls facing systemic inequality and cultural biases. The study suggests the implementation of internationally proven strategies to create a women-supportive ecosystem, combat harassment, and foster flexible working patterns. By cultivating a generation of empowered female educators, the paper aims to inspire and guide South Asian girls, fostering their confidence to pursue STEM ambitions and contribute to thriving STEM communities.

Iranian Women Shatter Stereotypes: Mahgard's Mission to Ignite a Scientific Revolution

Dr Arash Danesh[1,2], Dr Mohammad Taghi Mirtorabi[3,2], Mrs Mahdis Rezaei Niasar[3,2], Mrs Mahroo Bagherian[3,2], Mrs Hanieh Almasi[3,2], Mrs mehrnaz Zabayehi Najafabadi[3,2], Mrs Mohana Jafarinia[3,2], Mrs Sanaz Khanahmadi[3,2], Mrs Hakime Moini[3,2], Mrs Fatemeh Sadeghi[3,2], Mrs Seyyedeh Zeinab Masouni Zaviyeh[3,2]

[1]Institute for research in Fundamental sciences(IPM), Iranian National Observatory. [2]Mahgard. [3]Alzahra University

Abstract

Despite its rich cultural heritage, Iran faces challenges in science education, particularly for women. In the heart of Iran, where ancient cultural beliefs dance with a yearning for scientific exploration, a pioneering initiative named Mahgard is blossoming. Led by a fearless force of Iranian women physicists and astrophysicists, Mahgard is more than just an astronomy club; it's a vibrant community shattering stereotype and igniting a passion for science.

Driven by a collective belief in the transformative power of women in science, Mahgard tackles the challenges head-on. Leveraging technology and innovative events, they bridge the gap between traditional and scientific knowledge through storytelling. This ignites curiosity in all ages, empowering individuals and communities. They gamify the cosmos, transforming complex concepts into captivating experiences.

By seamlessly weaving traditional narratives with the wonders of modern science, they create immersive journeys under the stars, leaving audiences spellbound and yearning for more. This commitment to inclusivity extends beyond their events. Mahgard fiercely protects the intellectual property of all content it produces, fostering ethical knowledge dissemination and empowering the women within their ranks.

Mahgard is not just a community; it is a beacon of hope, a testament to the unwavering spirit of women who dare to dream and the power of science to illuminate even the darkest corners. Join them on this empowering journey and witness the stars align for a brighter future, where scientific exploration flourishes and cultural heritage finds harmony with the boundless potential of the human mind.

The fight against gender stereotypes begins in the classroom

Dr. Clementina Sasso[1], Dr. Silvia Galano[2]

[1]INAF-Osservatorio Astronomico di Capodimonte. [2]Department of Physics "E. Pancini", University of Naples Federico II

Abstract

Only 21% of all IAU members are women. While not all astronomers and astrophysicists are members of the IAU, this data is interesting because if we look at the percentage of women working in scientific or technological (STEM) fields around the world we get similar percentages. Women working in STEM fields are only 24% in the United States, 17% in the European Union, 16% in Japan, and 14% in India. This means that gender gap in STEM is a global issue. Many studies in Science Education show that a fundamental role in determining this phenomenon of horizontal segregation is played by gender stereotypes. These stereotypes influence individual choices and can lead girls not to choose to study STEM discipline because they are considered more suitable for male students. Gender stereotypes influence the individual throughout his or her life and are more effective in the early years. This means that to address this problem it is necessary to develop and implement strategies and actions suitable for young girls. Drawing on results in research in Astronomy Education, in particular on studies focused on gender stereotype in STEM, we have specifically designed a training course for teachers to help their students, in particular girls, in recognizing and deconstructing gender stereotypes in order to support them to make more informed and free choices about their study career.

Empowering Women in Astronomy for a Brighter Universe

Mr. Redait Basaznew

Space Science and Geospatial Institute (SSGI)

Abstract

This study focuses on the empowerment of women in the field of astronomy, highlighting the progress made towards achieving gender equality and the importance of inclusivity in shaping a brighter future for the universe. It explores the challenges faced by women in astronomy and showcases the remarkable contributions they have made to the field.

Despite historical disparities, female astronomers have defied societal barriers and made significant advancements in various branches of astronomy. The study highlights their groundbreaking research, discoveries, and leadership roles, which have expanded our understanding of the cosmos and paved the way for future generations.

The study also delves into the initiatives and organizations that promote the inclusion and advancement of women in astronomy. It discusses the role of mentorship programs, networking opportunities, and educational initiatives in nurturing talent and empowering women to thrive in the field.

By celebrating the achievements of women in astronomy and advocating for gender equality, this study aims to inspire more young women to pursue careers in this captivating field. By fostering an environment of inclusivity and equal opportunity, we can unlock the full potential of talented individuals and collectively contribute to the advancement of astronomical knowledge.

Advanced Ethiopian women in Physics and Astronomy Focus Group.

Ms. Mehbuba Ahmed

Space Science and Geospatial Institute (SSGI), Ethiopia

Abstract

Africa has amazing potential due to natural and human resources for scientific research in astronomy and space science. At the same time, the continent is facing many difficulties, and its countries are now recognizing the potentials of astronomy, space science, and satellite technologies to improve their main socio-economic and environmental challenges. The status of physics, astronomy and space science in Africa has changed significantly over the past years [Povic, M. et al., 2018] . The world's largest radio telescope (SKA) project can be taken as an instance for the development of physics education, and its application in astronomy and astrophysics in Africa. Unfortunately, ensuring female participation in physics and astronomy, in Ethiopia and in Africa in general, is facing complicated challenges, ranging from developing appropriate curriculum to market demand. The influence of the market demand and unemployment rate in Africa is lowering the participation of female students in science. The absence of a good STEM curriculum and quality education, in turn, hide the importance and power of Physics education in innovation and job creation in Africa. The most difficult challenges are obtaining support from friends and family members, having not a good background, a lack of employment in the field, not being interested in science because they do not visualize their daily lives in it, not having enough information about science, and not communicating with experts in the field. One way to uncover this power of Physics, for women in the field is through teaching and mobilizing, informing society.

CHIA, a constellation of female Colombian Astrophysicists

MSc. Maria Gracia Batista

Universidad de los Andes, Bogotá, Colombia.

Abstract

In recent decades, there has been a positive trend towards increased participation of female astronomers globally. However, the situation in Latin America, including Colombia, remains complex. While the astronomy community in Colombia is growing, there is a noticeable lack of female representation. According to the International Astronomical Union, out of 33 astronomers affiliated with Colombian institutions, only 5 identify themselves as women. This gender disparity is particularly evident in academic positions, where only three female astronomers hold permanent positions.

In response to this gender gap, we created the CHIA network (Female Colombians doing research in astronomical sciences), established in 2019. The network aims to unite female astronomers both within and outside Colombia. Research revealed approximately a hundred Colombian women astronomers, ranging from undergraduates to associate professors, scattered across the globe.

Recognizing the importance of female role models, CHIA focuses on providing visibility to the research conducted by female astronomers and engaging in science dissemination and outreach activities to inspire the next generation of female scientists. Additionally, the network fosters a collaborative community to support and encourage the careers of female astronomers at all stages.

CHIA seeks to address the gender gap in STEM fields in Colombia by promoting representation, providing mentorship, and fostering a supportive environment. In this talk we would like to introduce our collective and the multiple projects we are developing with the aim to create a more equitable and inclusive environment using Astronomy as a fundamental tool of development in our country.

Breaking Barriers: The Role of Women in Astronomy

Dr. Dismas Wamalwa

Meru University of Science & Technology

Abstract

Women have made significant contributions to the field of astronomy throughout history, yet their achievements have often been overlooked or marginalized. This abstract explores the historical challenges faced by women in astronomy, including limited access to education and professional opportunities, as well as societal biases and stereotypes. Despite these obstacles, many women have made groundbreaking discoveries and advancements in the field, paving the way for future generations of female astronomers. This abstract also highlights the importance of promoting gender equality in astronomy and creating a more inclusive and diverse scientific community.

Using a Small Telescope Featuring a Wide Field of View for Space Situation Awareness

Dr Ahmed Moursi

National Research Institute of Astronomy and Geophysics(NRIAG)

Abstract

Space Situation Awareness (SSA) plays a pivotal role in monitoring and understanding the dynamic environment beyond Earth's atmosphere. This paper explores the utilization of a small telescope equipped with a Wide Field of View (WFOV) to enhance SSA capabilities. Traditionally, larger telescopes with narrow fields of view have been employed for space observation, limiting the ability to track multiple objects simultaneously. The integration of a small telescope with WFOV presents a novel approach to overcome these constraints. The study discusses the design and implementation of the small telescope, emphasizing the advantages of a wide field of view for increased coverage of the celestial sphere. By leveraging advanced optics and imaging technologies, the telescope enables rapid and comprehensive monitoring of space objects, including satellites, debris, and celestial bodies. The WFOV facilitates real-time tracking of multiple targets, improving the efficiency of SSA operations. Furthermore, the paper explores the potential applications of the small telescope in conjunction with existing space surveillance networks. The cost-effectiveness and portability of such a system make it an attractive addition to the current infrastructure, providing valuable contributions to global SSA efforts. The research also addresses challenges associated with data processing and analysis, proposing solutions to optimize the extraction of meaningful information from the vast amount of observational data generated. The paper highlights the presence of an existing optical system, offering a FOV of about 3.4˚ x 2.3˚. This system was established in 2019 at the National Research Institute of Astronomy and Geophysics, Egypt.

Identification of Potential Astronomical Sites in Ethiopia

Mr. Nebiyu Suleyman[1,2], Dr. Solomon Tessema[3,4]

[1]Ethiopian Space Science Society (ESSS). [2]Office of Astronomy for Education (OAE). [3]International Astronomical Union. [4]Ministry of Innovation and Technology

Abstract

In the future, Ethiopia may find the need to build new astronomical observatories to continue local programs and contribute to global survey projects. Astronomical site identification studies are critical for decision-makers to propose where to build astronomical observatories. Without the best site identification and selection for the telescopes, it's impossible to get good observations no matter how powerful the telescope may be. The observing quality of medium and large telescope observatories at optical and infrared is determined mainly by atmospheric transparency that depends on the metrological and topographic conditions. Because of these factors and the high costs of large telescopes and their implementations, Ethiopia must choose sites that are the best possible places for astronomical observations. Fortunately, the nation has many potential candidate sites with high plateau regions and mostly dry climates that are located near the equator. Exploiting these resources will create more opportunities for Ethiopia and the astronomical community.

The best possible candidates for astronomical observational sites in Ethiopia can be identified using the Analytical Hierarchy Process method integrated with Geographical Information Systems and remote sensing technologies. Mountain sites that are higher than 2,500m above sea level were ranked according to their metrological parameter values. The selection is based on the general principles that a good observatory site has a high elevation, little light & aerosol pollution, higher available clear nights, low precipitation, calmer wind, and low-temperature fluctuations. With Statistical analysis, the favorable sites are mainly found in the highlands of the Northern and Eastern parts of Ethiopia.

Astrochemistry in Africa: let's form our bond

Prof. Dr. Zainab Awad

Astronomy, Space Science and Meteorology Dept. - faculty of Science - Cairo University

Abstract

Astrochemistry is the field of astronomy that blinds astronomy with chemistry. It is also known as molecular astrophysics because it is based on the studied of molecular spectra we receive from different directions/ regions in the universe. Although astrochemistry is a relatively new field in astronomy (< 100 years old), the number of astrochemists continues to increase. Thanks to the new technologies that opened windows in all wavelengths to the largest chemistry laboratory ever; the universe, and motivated and attracted more astronomers to this field.

Africa is reach not only in its human resources and man power but it also possesses some astronomical facilities that operate in a wide range of electromagnetic spectrum from optical to radio. Of course, optical observations are the least important to astrochemistry due to atmospheric line overlapping, but other band such are radio will be of a great help in investigating and exploring the chemistry of the universe.

In this talk, I would like to highlight the efforts African astronomers put in their research with the lack of financial support and resources and also the challenges we may face under all of these bad economical situations we pass through. In addition, I hope to addresses the main facilities we have in Africa and how can we facilitate them and build a new network for African astrochemists under the umbrella of the Astronomical African Society. In this network, I hope that African astronomers, whether reside in their original countries or live abroad, join and help.

Real-Time Profiling of Atmospheric Parameters with Single Star SCIDAR using the Power Spectrum of Scintillation.

Youssef Errazzouki[1], Abdelfattah Habib[2], Abdelhadi Jabiri[3], Mohamed Sabil[4], Benkhaldoun Zouhair[1]

[1]cadi ayyad university. [2]Regional Center for Education and Training Professions Marrakesh. [3]jabiri@uca.ac.ma. [4]National School of Applied Sciences Beni Mellal

Abstract

Optical turbulence in the atmosphere significantly affects adaptive optics, high-resolution imaging, and site testing. The single star SCIDAR technique offers vertical profiles of these critical parameters, including the refractive index structure constant $Cn2(h)$, by analyzing the scintillation of single stars.

Our study presents a novel approach for real-time measurement of atmospheric parameters using Single Star SCIDAR. The key innovation lies in leveraging a modified power spectrum of atmospheric speckles, which exhibit more pronounced variations with altitude. By employing this modified spectrum, we compute an objective function and apply the Active-Set algorithm for minimization, resulting in accurate real-time vertical profiles of $Cn2(h)$. Processing time is swift, at around 3 seconds per profile, with a high recovery rate of approximately 95%.

To validate the reliability of our approach, we conducted simulations and compared results with data from sounding balloons. These validations affirm the method's accuracy and credibility, highlighting its potential across various practical applications, particularly in the domain of Adaptive Optics (AO) systems.

Given that AO systems heavily rely on precise atmospheric parameter knowledge to counteract turbulence-induced distortions, the availability of real-time vertical profiles empowers these systems to make prompt and accurate adjustments, ultimately leading to enhanced image quality.

Rubin's LSST: opportunities for worldwide democratization of astronomical research and public outreach

Professor Zeljko Ivezic

AURA/University of Washington

Abstract

The Legacy Survey of Space and Time (LSST), the first project to be undertaken at the new Vera C. Rubin Observatory, will be the most comprehensive optical astronomical sky survey ever undertaken. Starting in 2025, Rubin Observatory will observe the sky visible from its location in Chile every clear night for ten years. Using this 60,000 terabyte image dataset, about 20 billion galaxies and a similar number of stars will be observed close to a thousand times - for the first time in history, the number of cataloged celestial objects will exceed the number of living people. LSST data will be used for investigations ranging from cataloging potentially hazardous near-Earth asteroids to fundamental physics such as the characterization of dark matter and dark energy. LSST data will be available online and thus will signficantly contribute to the democratization of astronomical research and public outreach around the world. There are already thousands of scientists from many dozens of countries, large and small, who are preparing to actively participate in LSST's rich science harvest. I will summarize these ongoing efforts and discuss how LSST data could help development of astronomy in Africa.

Characterization of the optical properties of atmospheric turbulence:Application to the choice of the site of the future Observatory of Senegal

Ms Abdoulaye BA[1,2], Ms Papa Douta Tall[3], Ms Zouhair Benkhaldoun[2], Ms Mamadou Simana Dramé[3], Ms Aziz ziad[4]

[1]Cheikh Anta Diop university of senegal/Caddi Ayad University of Morocco. [2]Caddi Ayad university of Morocco. [3]Cheikh Anta Diop university of senegal. [4]Nice sophia university

Abstract

Modern astronomy demands ever increasing performance from its instrument
A major obstacle for ground-based observations is the micro-fluctuations of temperature in the atmosphere which, modifying the refractive index of the air, randomly scramble the propagation of optical waves and cause a loss of information. The choice of a site for a future observatory is crucial for the long-term development of national astronomy. Thus, the image quality or seeing has become one of the criteria retained in the final decision making for the choice of sites.

The prediction of atmospheric and turbulence conditions is of great interest for the astronomical community, However the use of a numerical approach becomes crucial for the characterization of atmospheric and optical turbulence conditions.

In this study, a numerical approach based on the Weather Research and Forecasting (WRF) of meteorological parameters (temperature, relative humidity, wind speed and direction) as well as the optical turbulence conditions (CN2) of the forecast model for all three target sites in Senegal. We also present the seeing obtained for each site and other integrated parameters of the vertical profiles of atmospheric turbulence.

Keywords: Atmospheric turbulence, Seeing, Weather Research and Forecasting

The impact of ground-based telescopes in the formation of the next generation of astronomers

Prof. Itziar Aretxaga

Instituto Nacional de Astrofísica, Óptica y Electrónica

Abstract

Hands-on observational astronomy is valued as one of the most important experiences by the alumni of the International Schools for Young Astronomers (ISYA) over the years. ISYAs are three-week long intensive schools that target specifically graduate students coming from astronomically underdeveloped countries and isolated groups. We recount our experience with tutoring that goes from a observations taken with optical telescopes through a few nights, to a few hours of remote observing experience in our program. The thrill of discovery through the access to the telescopes is an experience difficult to transmit through database analysis alone. Even remote real-time observing has a beneficial experience for the starting student in Astronomy.

Working towards an implementation of a robotic optical telescope.

Dr Mohamed fayed

National Research Institute of Astronomy and Geophysics

Abstract

This paper represents the implementations towards automating and scheduling astronomical observation of the 14-inch telescope. It is a German equatorial telescope and located at the Kottamia Astronomical Observatory (KAO). Using STX-16803 CCD camera and seven positions filter wheel, astronomers can acquire best observations. Recently, the dome has been automated to run in an automated mode slaving to the telescope. The control system includes weather station, monitoring system and extra sensors to provide unattended observations. The utilized software application is designed based on Python and comprises necessary self-decision making codes for protection. Therefore, the developed hardware and software environment allow more efficient remote control without physical attendance.

Europlanet Telescope Network for promoting international collaboration

Prof. Grazina Tautvaisiene

Vilnius University

Abstract

The Europlanet Telescope Network (EPN-TN), launched in 2020, is a network of small and medium size telescopes. The EPN-TN currently comprises 18 observatories with 46 telescopes ranging from 40 cm to 2 m in size. The network is open for new infrastructures. Observatories from Africa are particularly welcome. In 2024, the network is entering a new sustainable operation phase after the end of EC funding via the Europlanet 2024-Reseach Infrastructure project. The network is fostering the international collaboration. Majority of the observatories provide free of charge observing time for the collaborative projects. The overview of the network and success stories will be presented.

Light pollution trend at the Kottamia Astronomical Observatory

Mr. Mohamed Aboushelib[1], Prof. Abdel Fady Morcos[1], Prof. Samir Nawar[1], Prof. Osama Shalabiea[2], Prof. Zainab Awad[2]

[1]National Research Institute of Astronomy and Geophysics. [2]Astronomy, Space Science and Meteorology Department, Faculty of Science, Cairo University

Abstract

Light pollution is a major concern for many scientists, especially astronomers. Astronomical observatories are usually built in remote locations away from cities to avoid the impact of artificial light, but since 1970s, light pollution has started to become a threat due to development and urbanization. Kottamia Astronomical Observatory in Egypt has one of the largest telescopes in Africa and the largest in the Middle East and North African region. Due to the constructions of the new cities near the observatory since 1992, the night sky brightness at the Kottamia observatory has changed due to the light glow resulting from these cities. In order to study the impact of artificial light on the Kottamia observatory, the sky brightness variation is obtained for the interval between 2012 to 2023 using VIIRS/DNB onboard Suomi NPP satellite. The light pollution trend over the Kottamia observatory was studied and the effect of each city's artificial light was addressed through the same interval. The data showed that light pollution at the Kottamia site has been increasing since 2013 mainly due to the sky glow from New Cairo and the New Administrative Capital cities. During the last three years, the sky brightness at the Kottamia was found to be decreasing which is a result of replacing the low and high pressure sodium lamps with warm light-emitting diode lamps which is not detected by the satellite's sensor. We believe the artificial light at the Kottamia observatory will get worse in the near future which requires immediate action.

Characterizing and Comparing Astroclimatic Parameters in the free Atmosphere of the MENA Region Through NCEP/NCAR Reanalysis: A Comparative Study

PhD Youssef Hach[1], PES Zouhair Benkhaldoun[1], PA Mohamed Sabil[2], PES Abdelhadi Jabiri[1]

[1]Laboratoire de Physique des Hautes Energies et Astrophysique (LPHEA), FSSM, Université Cadi Ayyad, Avenue Prince My. Abdellah, BP 2390, 40000, Marrakech, Morocco. [2]Laboratoire de Physique des Hautes Energies et Astrophysique (LPHEA), FSSM, Université Cadi Ayyad, Avenue Prince My. Abdellah, BP 2390, 40000, Marrakech, Morocco and Ecole Nationale des Sciences Appliquées, Ecole Supérieure de Technologie, Université Sultan Moulay Slimane, BP 591, Av. Mohamed-V- Hay Takaddoum, 23000 Beni Mellal, Morocco

Abstract

In the absence of in situ measurements, it is crucial to develop analytical tools that enable large-scale site prospecting. Here, we present a study conducted in our laboratory aimed at contributing to the selection efforts of the best possible astronomical observatory sites in the MENA region.

Accurate characterization of wind distributions and optical turbulence is essential for selecting suitable astronomical observatory sites.

This research presents two studies focusing on the characterization of astroclimatic parameters using NCEP/NCAR reanalysis data spanning two time periods: a 5-year period from 2011 to 2015, and a period of 2011 year extending Junuary 1 to December 31. **The first study aims to characterize astronomical sites in the MENA region by conducting a comparison based on meteorological parameters such as wind speed, its direction, pressure and temperature. Statistical analysis of 200-mbar wind speed averages across various MENA locations reveals the same seasonal behavior for Mishbah and Shams sites with the lowest values in summer and the highest values in winter. In contrast, the mid-latitude sites, Aklim and Chelina, present an inverse seasonal behavior .**

The second study focuses on the same six MENA sites from the main list and delves into additional aspects related to atmospheric turbulence. Indeed, we examined the integral parameters and the statistical analyzes reaveled promising values for the Deiba site which recorded a value of 8.77 ms for the coherence time and 1.54 arcsec for the isoplanatic angle. In addition, a good average seeing of 0.50 arcsec was recorded for the Aklim site.

Building large Telescopes and Site Tests

Prof. Abd El Fady Morcos

National Research Institute of Astronomy and Geophysics. The National Committee for Astronomy and Space, Acadmy of Scientific Research and Technology

Abstract

Site selection is an extensive multi-disciplinary effort integrating astronomical, environmental, geological, and social factors. Many researchers conducted to optimize location choices incorporates Multicriteria Decision Analysis (MCDA), utilizing techniques such as Geographical Information Systems (GIS) and the Analytic Hierarchy Process (AHP) for the evaluation of potential sites. But no one can neglect the key considerations and methodologies adopted for site selection, with a primary focus on ten criteria detailed in studies: sky transparency, night-sky brightness, photometric night fraction, light pollution, altitude, terrain slope, accessibility, seismic vulnerability, wind speed, and land use/land cover. The integration of satellite-based spatial data and GIS in MCDA provides a dynamic approach to assessing geographic variables over wide spatial extents. Global efforts also include the development of an Astronomy Suitability Index (SIAS) designed to enumerate and contrast site potential globally, guiding global and regional astronomical communities. Adoption of these methods offers a refined procedural blueprint essential for astronomers, institutions, and governments seeking to enhance celestial observations by selecting optimal sites for optical-astronomical observatories.

Nowadays, The National Research Institute of Astronomy and Geophysics (NRIAG) at Egypt starts the first step in establishing a new observatory at Sinai. The previous technique may be followed on the chosen place to perform the (ELOT).

The Lalibela , Ethiopia Infrared and Optical Telescope Site Test Status and Future Science plan

Dr Solomon Tessema[1,2], Dr Yikdem Mengesha[3], Mr Dereje Getachew[4], Ms Nigest Getachew[5]

[1]Entoto Observatory and Research Center (EORC) Ethiopian Space Science and Geospatial Institute. [2]Ministry of Innovation and Technology (MInT). [3]Department of Physics, Mekele University, Mekele, Ethiopia. [4]Department of physics, University of Gonder, Gonder, Ethiopia. [5]Department of Physics, Bahir Dar University, Bahir Dar, Ethiopia

Abstract

The Ethiopian Infrared and Optical Telescope project is Located at Mount AbunaYosef, approximately 50 kilometers away from the revered old city of Lalibela—named for the Zagwe monarch Gebre Mesqel Lalibela of the 12th century. One of Ethiopia's northern most World Heritage Sites and popular tourist destinations. Another project that will advance deep space exploration and astronomy study in Africa, the Northern and Southern Hemispheres, and beyond is the Lalibela Infrared and Optical Telescope (1–5 meters) and above telescope project. Preliminary research conducted in the vicinity of Lalibela indicates that the following are potential: Mahe Terara, Gashena district; Mount AbuneYosef, Lasta district (4280 m above sea level); and Mount Abohaye gara, Gidan district (4140 m above sea level). It is expected to be one of the best astronomical research sites next to Chile and Hawaii. The project is owned and financed by a Consortium of Universities mainly Bahir Dar University, University of Gondar, Mekele University, Woldia University, Ethiopian Space Science Society, and Amhara Regional State and is open for international and contented universities and research institutes to join the consortium. The project will boost and add the impact of astronomical infrastructure on African socio-economic and environmental development in knowledge, technology transfer science discovery, and equally use of resources in space.

Egyptian Large Optical Telescope (ELOT): An Update

Prof. Yosry Azzam

National Research Institute of Astronomy and Geophysics

Abstract

As a result of constructing the new Egyptian administrative capital near the Kottamia observatory, the Egyptian astronomical society asked for another site for building a new telescope which was approved by the government. The new telescope is expected to have a 6.5-m aperture.

Although modern large ground-based telescopes are complex and requires expensive pieces of research equipment, a crucial part of their design and effectiveness are affected by their location. Future Egyptian Large Optical Telescope (ELOT) is expected to help astronomical community in Egypt and worldwide to fill the observational gab between Europe in the north and South Africa in the south and between Asia at the east and Chile at the west.

Two sites have been selected which are good candidates for astronomical sites based on some physical and meteorological parameters using satellite data. The first site is located at south of Senai Peninsula, while the other is located near red sea northwest of Hurghada city. Although the prevailing meteorological conditions over these two sites have been investigated (noticed very similar to each other) and found suitable to install ELOT on, the red sea site has been lately excluded due to its terrain difficulties and the fear of urban and touristic extensions. As a result, characterization of Sinai site using specific instruments has started.

In this talk I will introduce the recent updates in the site selection and testing process along with the difficulties and challenges facing the process towards constructing of the Sinai observatory.

Protecting optical observatory sites from the growing satellite constellation interference

Dr. Constance Walker

IAU CPS. NSF's NOIRLab

Abstract

The deployment of communication satellite constellations in Low Earth Orbit (LEO) may represent a valuable step forward in improving world connectivity. However, the sun-reflected luminosity and radio-frequency emissions from a large number of satellites can have a serious impact on astronomical observations, as well as on the pristine appearance of the night sky. In recent years, various strategies for co-existence in terms of optical astronomy have been developed. There are now better models and data for satellite brightness, which are key to enabling mitigation, active avoidance, or use in compliance checks. Future observations of commercial LEO satellites will determine, for instance, whether some coatings and Bragg mirrors on reflective surfaces of Starlink satellites will help and how well. For spectroscopy, better modelling and understanding of satellite spectra will enable the emission from satellites to be calibrated out of astronomical data. Autonomous imagers on large spectroscopic facilities can help identify when an exposure was contaminated. For observatories, there are software solutions for streak detection and elimination that may help. During the presentation, we will discuss mitigation strategies through software and observation and provide updates in the areas of policy, industry and community engagement, some of which is being led by the IAU Centre for the Protection of the Dark and Quiet Sky from Satellite Constellation Interference.

Korea Microlensing Telescope Network (KMTNet) for Multi-Messenger Astronomy: Key Results and Future Prospects

Professor Myungshin Im

Seoul National University

Abstract

Korea Microlensing Telescope Network (KMTNet) is a network of three 1.6-m diameter wide-field optical telescopes operated by the Korea Astronomy Space Science Institute. One of the three KMTNet telescopes is at the South African Astronomical Observatory. Here, we describe our collaborative efforts using this facility. Notable activities are the optical follow-up observations of transients such as the gravitational-wave sources and the KMTNet Synoptic Survey of Southern Sky (KS4), a BVRI imaging survey of the southern sky with few previous imaging coverages to provide reference images for future transient studies. We will describe KS4 and KS4 research highlights, including transient science, high redshift quasar, and galaxy cluster searches. We will also present our network of telescopes worldwide and the 7-Dimensional Telescope, a new multiple telescope system capable of performing time-series spectral mapping of the sky that started its operation in October 2023. We will discuss how we might be able to promote multi-messenger astronomy and other science collaborations through these facilities with observatories in South Africa and other African countries.

The Benefits of the Virtual Observatory to Under-served Communities

Dr Bruce Berriman

Caltech/IPAC-NExScI

Abstract

The Virtual Observatory (VO) is a global ecosystem of interoperating services that connect worldwide data archives. The VO is implemented in all major astronomy archives through common interfaces developed by the 22 members of the International Virtual Observatory Alliance (IVOA). It was founded in 2002, and the latest members, the SKA Observatory and the Kazakhstan Virtual Observatory, joined in 2022. The VO offers access to data on FAIR principles and from its inception has supported Open Science. The VO acts a democratizing influence in astronomy: it provides equal access to worldwide public data sets to under-served communities as to large data centers, and enables international participation in scientific research and education. Thus astronomers from many different communities are positioned to participate in the big science questions emerging in astronomy in the 2020s, such as the interpretation of transient sources that will be measured in forthcoming missions such as Rubin. In addition, the IVOA has signed an MoU with the IAU Office of Astronomy for Development (OAD). Under this MoU, IVOA members took part in "Astronomy from Archival Data" which involved Educational Activities for Under-Graduate and Post-Graduate Students organized by Dr Priya Hasan. The IVOA plans to participate in future such educational events. The presentation describes how new communities may participate in Virtual Observatory science and educational activities. These include practices for developing VO-compliant data centers and archives, and education and training of developers and end users.

The Whole Earth Telescope and Stellar Seismology

Dr. Judith Provencal

University of Delaware. Mt. Cuba Astronomical Observatory

Abstract

The Whole Earth Telescope (WET) is an international collaboration of astronomers dedicated to the study of pulsating stars, with a focus on white dwarf stars. The WET was established in 1986 in the dawn of the development of the field of asteroseismology Asteroseismology uses the pulsation frequencies of a star as benchmarks to peer beneath the stellar surface and reveal interior structure, mass, rotation, and the possible presence of magnetic fields. The goal of the WET is to use the rotation of the earth as a platform hosting multiple ground based observing sites distributed in longitude to obtain 24 hr, continuous coverage of pulsating stars. The objective of continuous coverage is to eliminate aliases and resolve multiperiodic variations into their individual components. Accurate frequency identification is a vital component required for the success of asteroseismology. Ground based collaborations like the WET have a role to play in the age of space based missions such as TESS and the Vera Rubin telescope. This presentation will give an overview of the WET, the success of asteroseismology of white dwarf stars, argue for the importance of coordinated networks of small to moderately sized ground based telescopes, and present plans for the futures.

Abstract

Recently, the BRICS countries created a promising astronomy consortium, which was joined last year by some emerging countries, including two African countries, namely: Egypt and Ethiopia. Certainly, other African countries will join BRICS+ in the years to come. Thus, by pooling their efforts, emerging countries (BRICS+) are sure to quickly catch up with their technological delay in the field of astronomy, particularly through ambitious and large-scale projects.

Chile, due to the exceptional climatic conditions of its North, is recognized as the world capital of astronomy where all the largest consortia have settled there and applied all their know-how.

The official launch of BRICS (and then its expansion to other countries; BRICS+) is welcomed as an excellent opportunity to think big in the development of astronomy. China showed great determination by being the first southern country to settle by force and astronomical means in Chile, thus opening a possible opportunity for BRICS+ astronomers.

Ambitious astronomical instrumentation is essential for the future of Astronomy and Astrophysics. Access to existing facilities is becoming more and more difficult because of saturation. Existing programs like the VLT-I/ELT and their instruments necessitated decades of collaboration between international institutions. It is therefore necessary for the BRICS+ astronomical community to collaborate together on

ambitious projects without wasting time in order to offer a new pole with new opportunities for the researchers. This pole (BRICS-SO), in addition to attracting highly qualified people, will also help train new generations in all our countries, and encourage exchanges and collaborations.

Uzbek-Indian Cooperation in Astronomy: Opportunities for Expansion to Africa

Prof. Alisher S. Hojaev

Ulugh Beg Astronomical Institute

Abstract

The connection between the astronomy of Uzbekistan and India can be traced back to ancient times: in particular, the experience of the *Ulugbek Observatory* in Samarkand was used during the construction of the *Jantar Mantar* observatories in India. A new stage of active cooperation began in 2021 with a three-year project to search for and study variable stars in clusters, associations and beyond, supported by the Ministries of Science and Technology (India) and Innovative Development (Uzbekistan). The project initially involved the Aryabhatta Research Institute of Observational Sciences (*ARIES*) on the part of India and the Ulugh Beg Astronomical Institute on the part of Uzbekistan. As for the scientific part of the project, time-domain observations of 15 star clusters, 14 cataclysmic and a number of other variables (flare star, novae, supernovae, binaries, etc.) were carried out, some of the results of which have already been published in peer-reviewed journals. During long trips to *ARIES*, young Uzbek astronomers gained experience in observations with their 3.6-meter active telescope (a similar 4-meter telescope is planned to be installed in Uzbekistan). The Indian Institute of Astrophysics, Tata Institute of Fundamental Research, CRIST University, etc., who intend to create a modern polarimeter for Uzbekistan, have expressed a desire to join the next stage of cooperation from India. The experience of our cooperation will be useful for African astronomers. We are also open to joining them in cooperation, which subsequently, after the completion of the 70-meter radio telescope in Uzbekistan, can become multi-wave.

The Oukaimeden observatory and its operation in robotic and remote mode: An inspiration for the creation of other similar observatories in several African countries.

Professor Zouhair Benkhaldoun

Oukaimeden Observatory, Cadi Ayyad University, Marrakech Morocco. High Energy Physics and Astrophysics Laboratory (LPHEA), faculté of Science Semlalia, Cadi Ayyad University, Marrakech Morocco

Abstract

The Oukaimeden Observatory represents a pioneering model in astronomical research, operating with unparalleled efficiency in both robotic and remote modes. Its distinctive features, including cutting-edge robotic systems and remote operation capabilities, set it apart as a beacon of innovation in Africa's scientific landscape. This abstract highlights the observatory's exceptional achievements and its role as a catalyst for scientific collaboration and capacity building across the continent. Through strategic partnerships, workshops, and seminars, the observatory fosters the growth of scientific communities beyond its borders, contributing to a vibrant ecosystem of astronomical research in Africa. Furthermore, its strategic location in the High Atlas Mountains provides optimal atmospheric conditions for celestial observations, enhancing the quality of data collected. By sharing insights and best practices with international partners, the Oukaimeden Observatory exemplifies the transformative potential of scientific collaboration in advancing our understanding of the universe. As a speaker invited to this international conference, I am honored to present the Oukaimeden Observatory as a shining example of scientific excellence and innovation in Africa, inspiring the creation of similar observatories and fostering a new era of astronomical exploration on the continent.

Abstract

In addition to the Oukaimeden Observatory for VLT and the Aklim site for the European Extremely Large Telescope (E-ELT), which have been selected for site testing campaigns, we introduce a promising new astronomical site: Tassemit, situated in the High Atlas Mountains of Morocco. Tassemit is located at geographic coordinates 32°18'0" North and 6°15'0" West, boasting a large plateau at an altitude of 2300m.

This study begins with a comprehensive introduction to the Tassemit site, followed by a detailed statistical analysis of key meteorological parameters including air temperature, barometric pressure, relative humidity, and wind speed and direction. These crucial data points are derived from the ECMWF Reanalysis v5 (ERA5).

Moreover, the study delves into the analysis of parameters such as Cn2, free Seeing, Coherence time, and isoplanatic angle, spanning a period of 10 years. The initial findings underscore the potential suitability of the Tassemit site for future astronomical observations.

Stellar-scale astrophysics with optical telescopes using HBT interferometry

Dr Michael Backes[1,2], Dr Jonathan Biteau[3], Dr Colin Carlile[4], Dr Hambeleleni Davids[1,2], Dr Dainis Dravins[4], Mr Michele Fiori[5], Dr Tarek Hassan[6], Dr Eli Kasai[1], Dr David Kieda[7], Dr Michael Lisa[8], Dr Prasenjit Saha[9], Ms Naomi Vogel[10], Dr Roland Walter[11], Dr Luca Zampieri[5], Mr Andreas Zmija[10]

[1]University of Namibia. [2]North-West +University, South Africa. [3]IJCLab Orsay, France. [4]Lund University, Sweden. [5]INAF, Italy. [6]CIEMAT, Spain. [7]University of Utah, USA. [8]Ohio State University, USA. [9]University of Zurich, Switzerland. [10]FAU Erlangen-Nuernberg, Germany. [11]University of Geneva

Abstract

The Hanbury Brown and Twiss (HBT) effect is a basic process in quantum optics, but it was actually developed (in the 1950s) in the context of stellar astrophysics. Recent years have seen rapid developments in using the HBT effect to resolve mas and sub-mas scales in stars (commonly referred to as stellar intensity interferometry) through deploying new-generation photonics and electronics to existing optical focal planes, even with very modest image quality. A good example are recent measurements of sub-mas stellar diameters from H.E.S.S. in Namibia (which is primarily a gamma-ray telescope, but can also operate as a stellar intensity interferometer at visible light). Observations in stellar astrophysics have so far been overwhelmingly spectroscopic, and hence the availability of spatial resolution opens up many new research opportunities. Almost any optical telescope can contribute to the new research questions (i) by providing simultaneous spectroscopic observations, especially in the case of interacting systems, or (ii) by deploying suitable instrumentation along with another nearby telescope, to carry out stellar intensity interferometry, (iii) similar, but using multiple segments of a single large telescope.

The Southern African Large Telescope: Governance and Future Initiatives

Professor Brian Chaboyer

Southern African Large Telescope. Dartmouth College

Abstract

The Southern African Large Telescope (SALT) is a 10-meter optical telescope located in Sutherland, South Africa. SALT is an private South African corporation with a number of institutional shareholders from 5 different countries. The governance of the telescope was specified by a shareholders agreement, signed in 2001 by the institutional shareholders and updated on occasion. The shareholders funded the construction of the telescope, and continue to fund its operations. The telescope is operated by the South African Astronomical Observatory (SAAO) under an operations agreement between SALT and SAAO. In my presentation, I will discuss the corporate governance structure of SALT, highlight SALT's strategic vision for the next 10 years, and opportunities for investments by new institutions.

The ATOM telescope: Enabling simultaneous multi-frequency observations throughout the entire electromagnetic spectrum in Africa

Prof. Stefan Wagner, MSc Felix Jankowsky

LSW, ZAH, U. Heidelberg

Abstract

The ATOM (Automated Telescope for Optical Monitoring) telescope, a fully robotic 0.8m telescope, co-located with the HESS Gamma-ray telescopes in Namibia has been used to enable simultaneous optical and gamma-ray observations with HESS and to provide triggers for time-domain studies. Its operations are extended to facilitate joint time-domain programs with MeerKAT+ observations and will thus serve for radio-optical-gamma ray monitoring and ToO observations.

The telescope is equipped with a multi-purpose instrument, enabling simultaneous multi-band observations, polarimetry or high-time-resolution monitoring, facilitating a wide range of science use-cases in time-domain studies.

This presentation describes the operations principle, the versatility of robotic observations of all instrument modes, dual-way trigger communication with facilities in other waveband regimes and operation experience from the past 15 years of operations.

Upgrading Helwan Satellite Laser Ranging Station in Egypt, Past and Future.

Dr. Mohamed Helali[1], Prof. Makram Ibrahim[2], Ass. Prof. Ahmed Magdy[3], Dr. Shafeeq Abdalazeez[3]

[1]National Research Instirute of Astronomy and Geophysics (NRIAG), Helwan - Egypt. [2]National Research Institute of Astronomy and Geophysics. [3]National Research Instirute of Astronomy and Geophysics

Abstract

Since the seventies of the last century Helwan SLR station instruments, which is a member of the International Laser Ranging Service ILRS network have been upgraded many times Starting from photography of Satellites with respect to the background stars using the Russian AFU and NAFA cameras passing through Ruby Laser along with a photomultiplier tube with Cesium clock, Nd: YAG laser with GPS and Photon Interval Counter to until the year 2007. Then, a wholly new Station has been built near by the old one at NRIAG, Helwan Egypt during the last three years in cooperation with the Chinese Observatories which is planned to start operation and observation of Satellites and space debris in 2024 both by laser and Electro - Optical telescopes. An Introduction, comparison, and future of both stations are shortly presented in this paper.

Towards Improved EHT Observations: Measuring Precipitable Water Vapour at Potential Sites for the AMT in Namibia.

Mr. Francisco Fenias Macucule[1,2,3], Prof. Michael Backes[1]

[1]University of Namibia. [2]University of South Africa. [3]Associacao Mocambicana de Astronomia

Abstract

The first images of the shadow of the central black holes in the radio galaxy Centaurus A and in our own Milky Way, by the Event Horizon Telescope (EHT), opened a new window of research into active galactic nuclei (AGN) as well as into black holes. Soon it became clear that for improved image quality particularly also temporal resolution, additional telescopes would need to be added to the EHT network of telescopes. The Africa Millimetre Telescope (AMT)
will close this gap by being the first telescope in Africa to observe at millimetre wavelengths and, by that, will enable imaging of Sgr A∗ with the "Eastern" sub-array of the EHT. Beyond those VLBI observations, the AMT will also operate as a single-dish telescope for flux monitoring of AGN and transient science. Observations at millimetre wavelength are strongly influenced by the amount of precipitable water vapour (PWV) in the atmosphere. Here we present the current status of investigations of the PWV content of the atmosphere at the H.E.S.S. and Mt. Gamsberg sites in Namibia.

South African Astronomical Observatory: The Intelligent Observatory

Prof. STEPHEN Potter[1,2], Dr Sunil Chandra[1], Dr Nicolas Erasmus[1], Mr Roufurd Julie[3], Mr Moloko Hlakola[1], Dr Carel van Gend[1]

[1]South African Astronomical Observatory. [2]University of Johannesburg. [3]South African Radio Astronomical Observatory

Abstract

The South African Astronomical Observatory (SAAO) envisions an Intelligent Observatory (IO) to elevate scientific support for the astronomical communities in South Africa, Africa and beyond. This necessitated strategic technological advancements, including the automation and remote operation of telescopes, alongside a comprehensive redesign of the existing Sutherland operations model. While time-domain and transient science serve as the primary research drivers, all other domains within astronomy will also see significant benefits from these advancements.

As of late 2023, Phase 2 of the program is underway, focusing on developing an upgraded operations model that facilitates collaboration and automation, with a particular emphasis on automating data products. Furthermore, our vision is to expand our Intelligent Observatory network by including additional facilities across Africa and perhaps beyond. This presentation will not only review the achievements of Phase 1 but also delve into the initial results of Phase 2.

Ground-based optical telescopes in Africa for attaining the UN sustainable development goals

Dr. Mirjana Povic

Space Science and Geospatial Institute, Ethiopia

Abstract

Astronomy is one of the leading sciences in the development of education, other fields of science, technology and innovation. It is therefore key to combating poverty in the long term and achieving the UN Sustainable Development Goals (SDGs). Africa has amazing potential due to its natural and human resources for scientific and infrastructure development in astronomy. The status of astronomy in Africa has changed significantly in recent years, becoming an emerging field across the continent, and never before has it been possible to use astronomy for development as it is today. This talk will summarise the current state of astronomy in Africa, focusing in particular on optical astronomy and optical telescopes, and how they can be of fundamental importance for achieving in the long term the UN SDGs for the benefit of our society as a whole.

Development of a renewable-based hybrid generation microgrid system with energy storage and intelligent control for the new Egypt large optical telescope astronomical observatory

Dr Mohamed Abdelkareem, Research Professor Yosry Ahmed

National Research Institute of Astronomy and Geophysics (NRIAG)

Abstract

Egypt is working on establishing a giant astronomical observatory in Sinai. It will involve the largest optical telescope in the North Africa and Middle East area having a main mirror of diameter 6.5 m. Consequently, to establish a new green energy-based astronomical observatory a hybrid generation microgrid system (HGMS) model encompassing solar Photo Voltaic (PV) generation system, Energy Storage System (ESS), and Diesel Engine Generation (DEG) system with intelligent optimal controllers empowering the new Egypt Large Optical Telescope (ELOT) is proposed in this research work. A detailed study of the solar PV generation system components, specifications, and sizing is introduced. As well, intelligent optimal controllers are designed by applying innovative optimization algorithms. The system performance is validated under several eventualities, including solar radiation, wind speed variations, as well as fluctuations of load. The system dynamic response and simulation results show that the proposed microgrid hybrid generation system and the optimized control scheme effectively reduce deviations in an acceptable very short time. For more validation, comparisons will be instigated.

[1]Institute for Astronomy, University of Edinburgh. [2]Turkana Basin Institute. [3]KOTI. [4]University of Leeds. [5]Technical University of Kenya. [6]Open University

Abstract

With its rare combination of equatorial location and abundance of arid areas with dark skies, Kenya presents huge opportunities for optical astronomy. In 2022, a team from the University of Edinburgh joined forces with the Kenya Optical Telescope Initiative to install a 40-cm optical telescope near Lake Turkana, on the site of the Turkana Basin Institute in Ileret. The telescope was originally installed to perform observations of the NASA DART mission's impact with an asteroid. The installation was successful and due to Kenya's privileged location and the lack of nearby professional optical observatories, the observations performed were among a few to capture the event live.

This telescope remains the largest optical telescope in Kenya and was subsequently used to train African students, adding an optical astronomy component to the Development in Africa with Radio Astronomy (DARA) training programme, which will continue for the next few years. Efforts are also under way to identify a more permanent observatory site in northern Kenya, including testing of several nearby mountaintops, with the long-term objective to install a robotic 1m-class telescope.

SKA Observatory: opportunities for Africa and challenges with new large satellite constellations

Federico Di Vruno

SKA Observatory

Abstract

This talk will describe the SKA Observatory in its first Phase and in particular the ongoing construction of the SKA-Mid telescope in South Africa and the plans to extend it to other African countries, highlighting some of the positive impacts that the observatory had in South Africa. For the second part of the talk I will describe how the current deployment of large satellite constellations is presenting an ongoing challenge to the SKAO due to radio frequency emissions and other optical telescopes by reflection of sunlight. To finalize I will describe how the SKAO, together with other astronomy organisations including the IAU are working at the UN level to support better regulation and mitigations and show the collaboration with SARAO and the South African administration is addressing this issue at the national level.

Dark Sky Protection in South Africa - a Potential Model for Other Observatories in Africa

Dr Ramotholo Sefako

South African Astronomical Observatory

Abstract

The South African Astronomical Observatory (SAAO) is a premier optical astronomy research facility on the African continent, and the national centre for optical and Infrared astronomy in South Africa. It is home to over twenty individual national and international telescopes, including the Southern African Large Telescope (SALT), the largest optical telescope in the Southern Hemisphere. It is one of the observatories with the darkest night skies in the world. I will give an overview of the measures that are in place to protect the dark sky resources at the SAAO, including some details about the existing legislation (the AGA Act, No. 21, of 2007) and related astronomy protection regulations and prohibitions around what is called the Sutherland Central Astronomy Advantage Area (SCAAA). I will also give some details on the challenges related to the implementation of the regulations and prohibitions, as well as the complexities related to the enforcement of compliance of these regulations within the SCAAA. Astronomy Management Authority (AMA), an entity within the Department of Science and Innovation (DSI), supported by the NRF-SAAO, is responsible for monitoring and enforcement of compliance within the SCAAA.

Impact of Meteorological and Seismological Parameters on Telescope Site Selection: A Case Study in Egypt

Dr Mohamed Darwish

National Research Institute of Astronomy and Geophysics (NRIAG)

Abstract

Selecting an optimal site for astronomical observatories is crucial for achieving high-quality observations and advancing scientific research. In this study, we investigate the influence of meteorological and seismological parameters on telescope site selection, focusing on a case study in Egypt. Through comprehensive analysis and modeling, we assess various meteorological factors such as Air Temperature, Relative Humidity, wind patterns, and Aerosol Optical Depth as well as seismic activity and ground stability. Our research integrates remote sensing data, and geological archives to evaluate candidate sites for astronomical observations in Egypt. Additional, Light pollution over the candidate sites was measured using the Visible Infrared Imaging Radiometer Suite (VIIRS) day/night band. By examining the interplay between meteorological and seismological conditions, we aim to identify mountains with favorable conditions for telescope installations, considering both short-term weather variations and the seismic history. The findings of this study provide valuable insights for astronomers, site planners, and policymakers involved in the establishment of observatories, contributing to the advancement of observational astronomy in Egypt and beyond.

Japanese collaboration with universities for ground-based optical/infraredobservations

Yumiko Oass

Saitama University

Abstract

In Japan, optical and near-infrared observations have been carried out using a variety of small to large telescopes, notably the Subaru Telescope.

The inter-university collaborative project "Optical and Infrared Synergetic Telescopes for Education and Research (OISTER)" between nine universities and the National Astronomical Observatory of Japan (NAOJ) is particularly distinctive.

Its principal scientific goals are observational studies in optical/near-infrared regimes for the optical counterparts of the gravitational wave and/or neutrino sources, as well as various other transient and astrophysical phenomena.

The additional objective is to nurture highly-skilled youths by offering opportunities for undergraduate/master/Ph.D. students to engage in not only extensive science activities but also productive educational programs, including on-site observations and instrumentation experiences.

This talk will feature a presentation of these Japanese projects.

Observations and user support at intermediate-sized and large optical telescopes: a detailed comparison.

Dr Igor Chilingarian

Center for Astrophysics | Harvard and Smithsonian

Abstract

For over a decade I have been providing scientific support for the users of the 6.5-m MMT telescope operated in Arizona. In parallel, I carried out my own observational campaigns in the optical/near-infrared, largely related to studies of galaxies and their central black holes. In this presentation I will review my personal experience of observing at many world's largest ground-based observatories (Keck, VLT, Gemini, Magellan, MMT) as well as with some intermediate-sized 2-4m class telescopes. I will compare the level of user support provided by different observatories at different stages of observational projects, from designing a project and carrying out observations to scientific data reduction. In my opinion, the latter stage (data reduction) remains the strongest challenge for the vast majority of observational astronomers and it is the main factor delaying publications.

Reincarnating and Fully Automating the SALT/SAAO Seeing Monitor, TimDIMM

Dr. Timothy Pickering[1], Dr. Lisa Crause[2], Mr. Nico van der Merwe[3]

[1]MMT Observatory. [2]South African Astronomical Observatory. [3]Southern African Large Telescope

Abstract

The SALT/SAAO seeing monitor, TimDIMM, was initially installed and commissioned in 2010/2011 and has been in operation since then. However, in recent years its hardware began to show its age and it was becoming increasingly unreliable. Work was done over the course of 2023 and early 2024 to replace the camera with a larger, faster, more sensitive CMOS device and replace the mount with one that has more robust internal safety mechanisms. The original, largely bespoke software was completely replaced with an off-the-shelf open source system based on the Ekos scheduler and INDI-compliant device drivers. The new system achieved routine, fully-automated operation in February 2024. Building the software around Ekos/INDI makes it easy to replace/upgrade hardware components of the system with minimal changes to the software. INDI supports a very wide range of hardware and it's rare nowadays for something to not be supported by INDI at all. As such, we have found Ekos/INDI to be a very promising foundation for building automated site testing/monitoring systems.

The Impact of Small Telescopes on Outreach and Education Activities in Egypt.

Ms. Ola Ali

National Research Institute of Astronomy and Geophysics

Abstract

Egypt's exceptional dark skies present a unique opportunity for astronomical exploration. Despite this, astronomy awareness remains limited, particularly in remote areas. To bridge this gap, the National Research Institute of Astronomy & Geophysics (NRIAG) has undertaken a dynamic initiative utilizing small, portable telescopes for impactful outreach and education programs.

This presentation explores the transformative power of these programs:

- **Sparking Scientific Curiosity:** NRIAG researchers conduct engaging observing sessions, directly involving students in celestial wonders. These programs ignite a passion for science, fostering STEM interest and critical thinking skills. We will showcase specific observing programs and educational activities designed to effectively utilize the telescopes.
- **Empowering Communities:** Telescopes serve as powerful tools for public engagement. NRIAG astronomers organize stargazing events, lectures, and workshops, fostering a deeper understanding and appreciation of science within the community. We will share successful community outreach initiatives that not only promote astronomy but also advocate for dark sky preservation.
- **Building the Next Generation of Scientists:** Smaller telescopes provide invaluable training platforms for aspiring astronomers. NRIAG's programs equip students with observational skills and hands-on experience, nurturing the next generation of scientific leaders in Egypt.

This presentation will highlight successful examples from NRIAG's outreach programs and discuss strategies to maximize the reach and impact of small telescopes. Our goal is to cultivate a thriving astronomy culture within Egypt, where everyone has the opportunity to connect with the wonders of the universe.

Unveiling the Night Sky: Assessing Light Pollution and Lighting Technologies around Oukaimeden Observatory

Phd Student HAMZA AIT ABDELAALI[1], Professor ZOUHAIR BENKHALDOUN[1,2,3,4,5]

[1]Cadi Ayyad University , Faculty of Sciences Semlalia , PHEA Laboratory. [2]Oukaimeden Observatory Director. [3]President of the Moroccan National Committee for Astronomy (MNCA). [4]President of the Arab Astronomical Society (ArAS). [5]President of Atlas Dark Sky Foundation

Abstract

In recent years,ground-based observatories have grappled with a burgeoning issue: artificial light pollution.This phenomenon has emerged as a significant contributor to the illumination saturating the Earth's atmosphere from celestial sources, exacerbating the challenges faced by these crucial facilities. Understanding the extent of this artificial light intrusion is paramount for observatories to effectively gauge the quality of their observing conditions.
The measurement of night sky brightness (NSB) and the systematic collection of data pertaining to lighting technologies are integral steps in this endeavor. By discerning the proportion of artificial light within the overall optical brightness of the night sky, observatories can better comprehend the scope of the challenge posed by light pollution. Moreover, monitoring NSB not only aids in controlling light pollution but also serves as a vital tool for evaluating the sky's quality for astronomical observations.This study endeavors to elucidate the findings gleaned from a comprehensive assessment of NSB data collected over two years utilizing the CoSQM instrument installed at the Oukaimeden Observatory.Through meticulous analysis, we aim to shed light on the temporal trends and spatial variations in NSB.Furthermore, we endeavor to augment our understanding by compiling data on lighting technologies employed in neighboring municipalities.Gathering measurements of lighting technologies, aims to delineate their respective contributions to light pollution and discern potential strategies for mitigating their adverse effects on astronomical observations.This study serves as a testament to the critical importance of monitoring NSB and assessing lighting technologies in combating LP and safeguarding the integrity of ground-based astronomical research.

Multispectral analysis of the night sky brightness for the Oukaimeden Observatory, Morocco

Phd Student HAMZA AIT ABDELAALI[1], Professor Zouhair Benkhaldoun[1,2]

[1]Cadi Ayyad University Faculty of Sciences Semlalia PHEA Laboratory. [2]Oukaimeden Observatory Director

Abstract

The expansion of electrification in protected areas where astronomical observatories are installed poses a major problem for astronomers in terms of light pollution impact. Each year, the International Dark-Sky Association (IDA) encourages communities, parks, and astronomers worldwide to preserve and protect the darkness of the sky in their observation locations by imposing strict constraints on lighting practices within these protected areas. Astronomers from the Oukaimeden Observatory, located in the Atlas Mountains region of Morocco, aim to establish an international dark sky reserve around their facilities to enhance and safeguard the quality of their astronomical observations. This study aims to present the current state of the night sky in the region and identify the main sources of artificial light using the latest version of the numerical ILLUMINA model.

Open-source software for managing telescopes, observatories, and science programs

Dr Mark Bowman

Las Cumbres Observatory (LCOGT)

Abstract

The advent of time-domain astrophysics and surveys generating real-time alerts are driving innovation in how astronomers access and use telescopes. Many require urgent follow-up observations to characterize the event and understand the phenomenon and underlying population. Enabling astronomers to request observations through software facilitates rapid follow-up and broadens access to telescope facilities. However, developing the software needed can require a substantial investment of effort. In this talk, I will present two open-source software packages developed by Las Cumbres Observatory, and general enough to work for any observatory.

The open-source Observatory Control System (OCS) project, provides a suite of software for managing the user-facing operations of an observatory. It includes applications for managing users, science proposals, observing requests, and scheduling observations, as well as storing and accessing science data; enabling easy access to the observatory through a web browser or software APIs. The OCS provides an out-of-the-box observatory control system, with the ability to adapt its behavior to match the specific constraints of a particular institute or telescope. The fully modular design allows an observatory to run only the components they find useful.

The Target and Observation Manager (TOM) Toolkit is a powerful system designed for astronomers to run their observing programs and to interface with other key astronomical services such as data archives, alert brokers, and observing facilities. The OCS integrates easily with the TOM Toolkit.

The OCS and TOM Toolkit are suitable for all observatories from manually-operated individual telescopes to networks of robotic telescopes.

BLACK HOLE TOM – AN AUTOMATIC TOOL FOR PHOTOMETRIC TIME-DOMAIN DATA

Mr. Przemysław Mikołajczyk[1,2], Prof. Łukasz Wyrzykowski[1], Dr. Paweł Zieliński[3], Mr. Krzysztof Kotysz[2]

[1]Astronomical Observatory, University of Warsaw. [2]Astronomical Institute, University of Wroclaw. [3]Astronomical Institute, Nicolaus Copernicus University Toruń

Abstract

We present a new automatic tool for time-domain astronomy – Black Hole Target Observation Manager (BHTOM) – developed under the OPTICON RadioNet Pilot programme. BHTOM is a coordination tool for a global network of telescopes capable of automated photometric data processing for time-domain and transient targets. The tool has been used to process around 150,000 observations of several hundreds of transients, primarily reported by the Gaia space mission. We demonstrate the main features and use cases of BHTOM and present improvements to be made in the near future. The examples of images and light curves presented here confirm the ability to process CCD/CMOS imaging data from multiple telescopes and a whole variety of instruments in an automatic manner. Our tool is the perfect opportunity to involve smaller observatories into large observing campaigns as our network of telescopes is approaching 100 members.

From Timekeeping to Sky-Sweeping: The Sociopolitics of Astronomical Observation

Hedy Goodman

Haverford College. St. George's School

Abstract

In an increasingly digitized era of astronomy, the optical observatory remains both understudied and of understated significance. The evolution of its design gave rise to early community models of astronomy and countless subsequent developments in the field. Throughout every external change, its purpose remains consistent as a space designed to observe the Celestial sphere from the sanctuary of Earth. I illustrate this chronologically; first by discussing variations of archaeoastronomical sites, and then transitioning to observatory development, both pre- and post-emergence of the telescope. Two case studies, a pair of present-day ground-based observatories, represent this history in contrasting forms. I consider a model where all modern observatories comprise one, complete spectrum, with Strawbridge Observatory, established 1833, on one end, and the ongoing, yet largely controversial, Thirty Meter Telescope project on the other. I intentionally select two contradictory cases and analyze them sequentially to acknowledge a counterargument to my broader belief. Placing their differences in both form and scientific caliber within the context of time, I draw parallels in the greater architectural processes and developments of observational astronomy. I interpret these patterns as evidentiary to the common foundational model that is rooted beneath all modern variations of the observatory. As such, I propose a model that comprises many observatory styles, yet categorizes them according to purpose. While no two observatories are alike, all of their informed design choices indicate a system of structuralism - and without the astronomer, there would be no brain at all.

Observing Stellar Occultations in Support of NASA Missions from Africa: Opportunities for African Participation

Anne Verbiscer[1], David Baratoux[2], Marc Buie[3], Maram Kaire[4], Amanda Sickafoose[5]

[1]University of Virginia. [2]French National Research Institute for Sustainable Development (IRD). [3]Southwest Research Institute. [4]Association for the Promotion of Astronomy in Senegal (ASPA). [5]Planetary Science Institute

Abstract

Two NASA missions, New Horizons and Lucy, have conducted extensive campaigns in Africa to observe stellar occultations by their respective flyby targets. Prior to the spacecraft flybys, stellar occultations can provide valuable information about the flyby targets, including size, shape, and albedo, as well as astrometric information to optimize encounter planning. In 2017, the New Horizons Project organized a campaign using portable and fixed optical telescopes to observe a stellar occultation by its flyby target, Kuiper belt object, Arrokoth, from South Africa. New Horizons sent portable telescopes to Senegal to observe another stellar occultation by Arrokoth in 2018. Two of NASA's Lucy mission flyby targets, Trojan asteroids Polymele and Orus, had stellar occultations visible from Senegal in 2020 and 2021, respectively. For each of these four events, local African students and astronomers participated in the campaigns, with support from the Association for the Promotion of Astronomy in Senegal (ASPA) and the African Initiative for Planetary and Space Sciences (AFIPS, africapss.org) for the three campaigns in Senegal. This presentation will summarize the campaign organization, outcomes, and future opportunities to observe stellar occultations from Africa.

Exploring the Sub-Second Transient Sky with Continuous-Readout Images and Neural Networks

Shar Daniels[1], Federica Bianco[1], Igor Andreoni[2], Ashish Mahabal[3]

[1]University of Delaware. [2]University of Maryland. [3]California Institute of Technology

Abstract

With the novel application of deep learning models to continuously-exposed astronomical data, we are creating tools to discover and reveal the nature of rapidly-evolving optical astrophysical phenomena. Phenomena that vary on this timescale include cataclysmic variables, blazars, occultations by solar system objects, and potentially the optical counterpart of Fast Radio Bursts. Yet, the evolution of optical astronomical phenomena at sub-second timescales is under-explored due to technical limitations in traditional observing modes which require seconds-to-minutes exposure and readout cycles. However, the nontraditional "continuous-readout" mode enables resolution at sub-second timescales by integrating the images of astrophysical objects along one spatial dimension. Analyses of these data require custom pipelines. We are developing neural networks for the analysis of a 450GB continuous-readout astronomical dataset sampled at 300 Hz from the Zwicky Transient Facility (ZTF). This poster will show the performance of CNN and transformer models on the ZTF data and outline our potential for detecting and analyzing rapid transients at scale.

The Rubin ToO program: public data open opportunities for involvement in Multi Messenger Astronomy

Dr Federica Bianco

University of Delaware. Vera C. Rubin Observatory

Abstract

The Vera C. Rubin Observatory is planning to enable a Target of Opportunity mode for Gravitational Wave (GW) follow-up, potentially expandable to other science cases. The public nature of the Rubin real-time alert data promises to democratize participation in Multi-Messenger Astronomy (MMA) by providing targets for follow-up observations using spectroscopy and photometry. With an unprecedented combination of large field of view (9.6 square degrees) and depth (r~24), the primary challenge post-Rubin ToOs will lie in sifting through an extensive pool of candidate sources. Wile spectroscopy remains the foremost method for pinpointing the genuine counterparts of GW events, the complementary use of multifilter time-series observations, feasible with smaller telescopes, can also eliminate false positives and reduce the size of the sample requiring spectroscopic follow-up (Bianco+2019, Ofek+2024). I will review the current plan for the Rubin ToO program and discuss how GW electromagnetic counterparts are expected to separate themselves from other transients in spectroscopy and time-evolved photometry

A low cost compact optical polarimeter as example of sustainable and accessible instrumentation

Dr Pere Blay, Elisa Nespoli, Vicent Martinez-Badenes, Nestor Sanchez-Doreste

ESICT, Valencian International University - VIU, Valencia, Spain

Abstract

We have designed a compact low-cost versatile optical linear polarimeter, suitable for medium to small sized telescopes, with the scientific goal to perform surveys to characterize the polarimetric properties of the galactic plane. Polarimetric measurements can add important information about the ISM, both in extension and composition, and indirectly about the local structure of the galactic magnetic field. We have developed a simulation package, based on Python HCIpy, that allows to perform instrumental characterization, accompanied by detailed optical analysis with Zemax Optic Studio simulations. The python package will be available via github. 3D printer ready files, to build the instrument container and adaptors, will also be released as well as recommendation on scientific quality optical elements. The whole project description and products will be made available for the scientific community in a way that it can be used as it is or as the baseline for further instrumental research and development.

Networking Telescopes: Prospects for Autonomous Follow-up of Discoveries from Future Surveys

David Buckley

South African Astronomical Observatory. Department of Astronomy, University of Cape Town. Department of Physics, University of the Free State

Abstract

In this talk I will outline the plans within the BRICS consortium and also within Africa to network observatories and telescopes for autonomous optical follow-up observations of objects discovered by the up-coming large survey missions. I will review the pioneering SALT transient programme, which since 2018 has been actively engaged in the observing transients across the electromagnetic spectrum. This has included discoveries from the eROSITA X-ray surveys and the Gaia missions. In preparation for the Rubin Observatory's 10-year Legacy Survey of Space and Time (LSST), due to start in 2025, it will be crucial to have automated networks optical telescopes to characterize the nature of new transient and variable object discoveries from the LSST. I will review the aims of a global flagship project, namely the BRICS Intelligent Telescope and Data Network (BITDN), whose aim is to co-ordinate robotic observations utilizing the various facilities available to the BRICS partnership. A similar African initiative – the African Integrated Observation System (AIOS) – will also be described. Both of these build upon the SAAO's Intelligent Observatory project, which will also be briefly reviewed.

An overview of site testing and site characterisation, as applied in the search for an astronomical site in Kenya

Dr Edward Graham[1], Mr Richard Vaughan[2], Dr Acacia Leakey[3], Prof Colin Snodgrass[4], Dr Cyrielle Opitom[3], Prof Paul Baki[5], Ms Susan Murabana[6], Dr Daniel Hillier[7], Mr Daniel-Chu Owen[6]

[1]University of the Highlands and Islands, Scotland. [2]InCA, Nairobi, Kenya.. [3]University of Edinburgh, Scotland. [4]University of Edinburgh, Scotland.. [5]Technical University of Kenya. [6]The Travelling Telescope, Kenya. [7]Head of Public Engagement with National Laboratories

Abstract

Astronomical site characterisation requires an understanding of atmospheric processes across a huge range of scales, extending spatially from millimetres to thousands of kilometres, and temporally from microseconds to decades, or longer. This is because atmospheric perturbations cascade, both upwards and downwards, through the various scales. As a result, astronomical site testing studies must overlap with the domains of (long-term) climate science, (everyday) nowcasting and numerical weather prediction, as well as the finer scales of micro-meteorology and atmospheric observation.

The first global atmospheric models of historic states of the atmosphere, known as reanalyses, became available in the early 2000s. Over the past twenty years these have improved considerably in resolution and accuracy, and today they remain the most accurate and most valuable resource of the synoptic scale climate. High resolution regional models, using reanalyses as boundary conditions, as well as local-scale site specific models have also provided significant advances. However, significant gaps remain in our ability to link up between the various scales of interest, and in the validation of the models with actual observations on the ground.

Beginning nearly two decades ago, the search for an astronomical site in Kenya programme has now reached the stage whereby the best three potential sites in northern Kenya have been identified. Over the coming 1-2 years, we plan to advance the site testing programme by installing automatic weather stations and all-sky cameras at the three candidate sites to directly monitor the weather and to validate met model simulations of their atmospheric conditions.

STRENGTHENING UNDERGRADUATE EDUCATION USING REMOTE TELESCOPES

Prof. Paul Baki

Technical University of Kenya

Abstract

ABSTRACT

An overview is given of physics/astronomy undergraduate studies in Kenya using remote telescopes for observations, otherwise known as Astro-lab. We discuss the opportunities and challenges encountered, skills developed and we propose innovative ways of addressing challenges. We have observed that the use of remote telescopes can improve students' scientific abilities, such as inquiry, problem-solving, data analysis, and communication, and increase their interest and motivation in astronomy and STEM fields. Moreover, they promote collaboration and information exchange amongst students and teachers from diverse institutions, regions, and backgrounds, fostering the growth of a global scientific community and culture, as well as diversity and inclusivity in astronomy. In the case of Kenya, remote telescopes are helping us build capacity in multi-wavelength astronomy and also for the Square Kilometre Array project.

The students' projects involved use of robotic telescopes from the Las Cumbres Observatory (LCO) to observe selected eclipsing binary stars. In this paper, we explore novelties, challenges and opportunities for robust science going into the future. We also examine how, through tracer studies, the skill sets acquired are shaping career paths of our graduates.

Leveraging Ghana's 32-metre radio telescope for astronomy training.

Dr Emmanuel Proven-Adzri, Dr Naomi Asabre-Frimpong, Dr Theophilus Ansah-Narh, Mr Albert Forson

Ghana Space Science and Technology Institute

Abstract

The Ghana Radio Astronomy Observatory (GRAO) has become a training centre for students who yearn for hands-on experience in radio astronomy. The site operates the 32-meter radio telescope which conducts research in 6.7 GHz methanol masers in star-forming regions, pulsars, giant stars, supernova remnants and Active Galactic Nuclei (AGN). During the DARA phase 2 project, it trained about 100 students from, Kenya, Namibia, Zambia, Botswana, Mozambique, Madagascar and Ghana. While at GRAO, the students had hands-on training in telescope observations in single-dish and VLBI modes, data reduction, radio frequency interference (RFI) measurements, and receiver and sun temperature measurements. Table-top radio telescope (TTRT) operation and optical telescope viewing were also part of the practical sessions. GRAO is open to more collaborations to bring its training facilities to a wider audience in Africa and beyond.

Exploration of spectroscopic techniques for Educational initiatives at the Oukaimeden Astronomical Observatory in Morocco

Phd MOHAMED AMRAR[1], pr Abdelmajid BENHIDA[2], Pr Fouad Sefyani[2], Pr zouhair BENKHALDOUN[1]

[1]Faculty of Sciences Semlalia, Cady Ayyad University. [2]Faculty of Sciences and Techniques , Cady Ayyad University

Abstract

This abstract presents an overview of the primary instruments utilized for acquiring spectroscopic and photometric data at the Oukaimeden Astronomical Observatory (OUKAIMEDEN), along with its pedagogical role in astronomical education. The focus of this poster is twofold: first, the description of the telescopes employed, and second, the educational initiatives facilitated by the observatory.

Situated at an altitude of 2700 meters in the Atlas Mountains, the OUKAIMEDEN Astronomical Observatory (J43) serves as a cornerstone for astronomical research and education in Morocco. As the first university astronomical observatory in the country, it provides a platform for student internships, scientific experimentation, and observation-based learning experiences, thus fostering the development of astronomy within the university and beyond.

At OUKAIMEDEN, the spectro-photometry data acquisition is facilitated by a sophisticated setup comprising two telescopes, namely the C14 Telescope and the ASA 10N Telescope. Additionally, the setup includes two CCD cameras, an injection lens and guiding unit, two optical fibers, a calibration unit, an Eshel spectrograph, and two computers for telescope control and data acquisition. This comprehensive instrumentation enables precise spectroscopic observations essential for various research endeavors.

Beyond research, the observatory plays a crucial pedagogical role, offering practical training sessions local and international high school and university master's students through laboratory sessions and training workshops focused on stellar spectroscopies. Furthermore, educational efforts extend to the detection of exoplanets using the Doppler effect, contributing to the advancement of both theoretical and practical knowledge in the field.

LCO remote telescopes as an Educational Tool in the study of star clusters

Dr Priya Shah, Prof Syed Najamul Hasan

Maulana Azad National Urdu University, Hyderabad, India

Abstract

In the absence of observational facilities and the era of archival data, students miss out on the opportunity of acess to a telescople, observation strategy and experience in data collection with LCO remote telescopes. To bridge this gap we conducted online and offline workshops where we discussed observations, photometry, plotting of HR diagrams for open and globular clusters. We demonstrated determination of distances and ages of open and globular star clusters.

Robotic Telescopes in University Education

Prof Syed Najamul Hasan, Dr Priya Shah

Maulana Azad National Urdu University, Hyderabad, India

Abstract

The use of Robotic Telescopes plays a very vital role in Education especially in places where access to telescopes is not possible. We shall describe our experience of the use of LCO Robotic Telescopes in Copperbelt University, Zambia with undergraduate and postgraduate students of Astrophysics. This can be made part of the Astrophysics Lab where students get data, perform photometry and do data analysis. We demonstrated the plotting of HR diagrams and projects with stellar variability that can be performed in such projects.

A closer sky - an astronomical observatory on your class

Ms Elisabeta Ana Naghi[1,2,3], Mr Dan Alin Nedelcu[4]

[1]member of the Romanian National Astronomy Committee. [2]national coordinator for astronomy education in Romania- NAEC. [3]inspector for mathematics and astronomy at Education Ministry, Romania. [4]Astronomy at Astronomical Institute, Bucharest.

Abstract

Berthelot Observatory is a Romanian astronomical facility belonging to Astronomical Institute of the Romanian Academy and dedicated to Space Surveillance and Tracking (SST) activities and Near-Earth Objects studies. Operational since 2018, the observatory hosts three telescopes (0.2, 0.4 and 0.5m diameter) operated on remote- or queue-mode. Astronomical facilities operated in remote mode provide students with an excellent hand-on experience on state-of-the-art instrumentation and software. With remote access to research grade observatories becoming ubiquitous, student will gain insights not only on modern subjects of astronomy but also on the inner working of an observatory, thus expanding the reach of this educational activity to the entire domain of STEM education. Before actual observations, students will learn about the protocols, networks and interfaces that bring the telescope's control on their desktops and will see the building blocks - optics, detectors, mount and dome being prepared for an observation run. Observations scheduling and tasking will introduce basic concept of astronomy - coordinate systems and celestial body dynamics alongside algorithms for planning and deconflicting concurrent operations. In this poster we will outline the outreach activities tailored for all educational levels, from primary school to basic research projects for universities students.

Education, Outreach and Research Using the Thai Robotic Telescopes B. Soonthornthum National Astronomical Research Institute of Thailand.

Professor Boonrucksar Soonthornthum

National Astronomical Research Institute of Thailand.

Abstract

One of the main missions of the National Astronomical Research Institute of Thailand (NARIT) is to promote and support hands-on astronomy activities for publics both in national and international levels.

Apart from the 2 main national astronomical Infrastructures of NARIT, namely the 2.4-m Thai National Telescope (TNT) and the 40- m Thai National Radio Telescope (TNRT) provided for frontier and in-depth astronomical research beyond the capabilities of using small telescopes, NARIT has yet established the Thai Robotic Telescopes (TRT) Network for disseminating opportunities on teaching capacity of remote observing facilities for universities, schools and publics.

The TRT have been distributed in 4 countries, namely the Republic of Chile, People's Republic of China, Australia and the United States. It is a remote control system which allowed universities, schools and publics to apply and access country-wide. The TRT Network is a powerful tool in driving human

capacity buildings in astronomy and supporting many frontier and in-depth astronomical research collaboration.

From City Lights to Starry Nights: Robotic Telescopes Enabling Accessible Education in Pakistan

Ms. Hira Fatima

National Center in Big Data and Cloud Computing, NED-UET, Karachi, Pakistan. Institute of Space Science and Technology, University of Karachi, Karachi, Pakistan

Abstract

Karachi, renowned as the 'city of lights,' stands as Pakistan's most cosmopolitan city. Despite its vibrant nature, the presence of astronomical observatories is limited compared to the vast number of academic institutes. Over the years, our observatory has welcomed students and teachers for observation and training sessions. Additionally, we have extended our outreach by bringing portable telescopes to various institutes and regions. The scarcity of local astronomical observatories, coupled with light pollution in urban areas and limited accessibility to remote observatories, underscores the critical role of robotic/online telescopes in education.

As partners with the Las Cumbres Observatory (LCO), we have leveraged their 0.4-meter robotic telescopes and cameras in our astronomy education initiatives. We have trained school teachers to utilize robotic telescopes, enhancing their teaching of STEM curriculum. Furthermore, we have invited university students studying physics, mathematics, and space science, along with their teachers, to participate in training sessions that supplement their existing courses, such as introduction to astronomy, astronomical instrumentation, observational astronomy, and data-driven astronomy. We look forward to extending this practice with the possibility of using other instruments like spectroscopes with robotic telescopes.

Employing robotic telescopes for astronomy education not only enriches the learning experience but also provides opportunities to promote accessibility, inclusivity, equity, and a borderless approach to astronomy. In this presentation, I will discuss our journey of utilizing LCO robotic telescopes in education, highlighting the milestones we have achieved, the challenges we have faced, and the valuable lessons we have learned along the way.

Connecting Skies: The Evolution and Impact of Global Hands-On Universe (GHOU) in Astronomy Education

Prof. Hassane Darhmaoui

Al Akhawayn University in Ifrane

Abstract

The Global Hands-On Universe (GHOU) initiative has its roots in the early 1990s when astrophysicist/educators Alan Goud and Carl Pennypacker pioneered the "Hands-On Universe" (HOU) concept at the University of California, Berkeley. Their vision aimed to revolutionize astronomy education by enabling direct student engagement with real astronomical data and tools, departing from traditional textbook-based learning. Initially, HOU focused on providing access to telescopes, astronomical data, and software tools for analysis, primarily targeting teachers and students.

As the HOU program gained traction and expanded beyond its origins at Berkeley, it underwent a transformative evolution into the GHOU initiative. This shift marked a significant step towards breaking geographical barriers and promoting cooperation in astronomical education.

GHOU's mission evolved to encompass various facets of education, including the training of teachers in modern tools and resources for science education, the development of innovative curricula, and the facilitation of international scientific projects involving students. GHOU facilitated students' remote access to telescopes and astronomical data, democratizing access to scientific inquiry and enabling participation from students of diverse backgrounds.

Over the years, GHOU has continuously adapted to technological advancements and evolving educational practices. By forging partnerships with educational institutions, scientific organizations, and government agencies worldwide, GHOU has extended its impact and reach, further solidifying its position as a leader in astronomy education. Today, GHOU remains dedicated to empowering students and educators, fostering a deeper understanding of the cosmos, and inspiring the next generation of scientists and space enthusiasts worldwide through its innovative programs and collaborative endeavors.

PASEA: Inspiring Future STEM Leaders in Africa via Remote Observing Projects

Dr. Linda Strubbe[1], Dr. Heidi White[2,3], Dr. Jielai Zhang[4,5]

[1]Strubbe Educational Consulting. [2]Université de Montréal. [3]Trottier Institute for Research on Exoplanets. [4]Swinburne University of Technology. [5]ARC CoE for Gravitational Wave Discovery

Abstract

Robotic telescopes offer a valuable opportunity for students from under-resourced areas to grow their interest in astronomy and build scientific skills. In this talk, we describe a robotic telescope educational initiative from the Pan-African School for Emerging Astronomers (PASEA). PASEA is a biannual short course in astronomy for African university students, held 5 times since 2013. PASEA's vision is to build a critical mass of astronomers in Africa, and exchange ideas about teaching across continents.

In 2022 PASEA held a special online initiative called the Alumni Research Program (ARP) for ~60 undergraduate students from around Africa, focused on investigations of variable stars using the Las Cumbres Observatory (LCO) telescope network. The program was designed using principles from education research to help students build their scientific identities and skills. ARP began with a workshop on Python programming and data science skills. Next, students worked in small groups to collaboratively plan and request LCO observations of short-timescale transient/variable targets drawn from publicly available databases, with the goal of identifying the type of variable star.

Students performed basic photometry and light curve analysis on their LCO observations using specially-created Jupyter notebooks with Google CoLab, which the team has made publicly available on github. Student groups shared their findings with their peers through creative projects. ARP students expressed highly positive feedback, and the program received many more applications than we could accept. ARP demonstrates the great interest and value of robotic telescope-focused educational initiatives for supporting future scientific leaders in Africa and beyond.

Evaluation of Astronomy Education and Outreach Projects -- What, Why and How?

Dr. Linda Strubbe

Strubbe Educational Consulting

Abstract

As astronomy educators, we all have beautiful visions for how our astronomy education and outreach projects can make positive change in the world. Working towards our visions, it's important to ask, "How is my project going? Is it working well towards my vision, and what could make it work even better?"

Evaluation is the work of answering these overarching questions. Evaluation involves (1) articulating project goals, values, and desired outcomes along the way; (2) designing evaluation questions connected to our goals, and instruments to gather data to help answer those questions; (3) gathering and analyzing the data; and (4) bringing all together to give an evidence-based view of how well the project is achieving its goals, the project's impact on the world, and feedback for how the project can improve and do even better.

Designing projects with evaluation in mind is a key part of supporting our projects' success, so we can make informed decisions as the project goes along. You are probably already doing some evaluation as part of your education and outreach efforts. It can also be helpful to work with an External Evaluator (like me!), who specializes in designing and implementing evaluation, can offer an outside perspective, and help keep evaluation in focus throughout the lifecycle of the project. In my poster, I'll share resources to help you design and implement your own evaluation, and offer examples from my work as an External Evaluator on a variety of physics and astronomy education projects (Strubbe Educational Consulting: https://sites.google.com/site/lestrubbe/evaluation).

STEM education using remote observing facilities, several successful practices in China

Dr. Chenzhou Cui[1], Dr. Shanshan Li[1], Dr. Dongwei Fan[1], John Baruch[2], Xing Gao[3], Yujie Zhang[4]

[1]National Astronomical Observatories, Chinese Academy of Sciences. [2]Leeds Beckett University, UK. [3]Urumqi No.1 Senior High School, China. [4]Lijiang Gemini Observatory, China

Abstract

As technology and products continue to advance, there are increasing numbers of telescopes and other facilities providing remote observing services. The setup of remote observing systems is becoming more convenient, and the operation of remote observing is becoming easier. The level of intelligence in every aspect of the above process is constantly improving. In addition to meeting the scientific requirements of professional astronomers and the interests of amateur astronomers, remote observing facilities have also contributed a large amount of STEM science education resources. This talk will share the achievements and experiences of the application of remote observing facilities in STEM education through several specific examples, including the Citizen Science Project of Chinese Virtual Observatory (China-VO), the discovery of new celestial bodies at Xingming Observatory, the facility sharing platform at Lijiang Gemini Observatory, and the astronomy teaching through Bradford Robotic Telescope.

Global Sky Partners: creating an equitable, scalable and sustainable education programme with robotic telescopes

Dr Edward Gomez

Las Cumbres Observatory

Abstract

Astronomy is a fascinating science, capable of inspiring many thousands with a single picture. However, for a deeper change in people's way of thinking, inspirational pictures alone are not enough. We wanted to create a programme which did not only cater to the self-selected audiences, who are already fascinated by astronomy or ones led by an educator who has astronomy experience. These are often only available to privileged audiences, like private schools or astronomical societies. There are many tools which can be used to perform authentic astronomy investigations, well structured educational projects or even innovative artistic projects.

The **Global Sky Partners** is the flagship educational project from **Las Cumbres Observatory**. It addresses the key question of how to run an efficient and sustainable education programme in astronomy. Las Cumbres Observatory is a homogeneous network of 25 telescopes, across 7 professional observatory sites. Global Sky Partners uses the LCO education network of 10 x 0.4m telescopes, with an audience of (on average) 60,000 individuals each year, from over 40 countries.

PROPOSED REMOTE/ROBOTIC TELESCOPE BY THE UNIVERSITY OF ZULULAND

Prof Aroonkumar Beesham, Prof Thulani Jili

University of Zululand

Abstract

The University of Zululand (UNIZULU) is situated is a predominantly rural area, and undergraduate and high school learners are not exposed to astronomy with telescopes. Together with several other academics, we have succeeded in getting a 0.45 m optical telescope funded by the Department of Science and Technology. We are very excited about this development, having already secured a suitable site for the installation a mountains, 20 km east of the Eshowe area near UNIZULU. The construction of the road leading to the mountain has started and this realization is due to our cooperation with the local Mlalazi Municipality. The university has committed itself to building the telescope housing as well as accommodation for researchers.

It is anticipated that the telescope will have a dual purpose, viz., performing remote/robotic observation-based projects, and working hands-on with the telescope on site. Undergraduate modules in astronomy have been developed and submitted to the relevant external bodies for their endorsement. The telescope will be used for practical purposes.

The UNIZULU Science Centre at Richards Bay nearby carries out STEM activities in astronomy amongst school and undergraduate students. We will work closely with the centre to enhance STEM education.

Having already carried out a pilot project at UNIZULU successfully in the use of remote/robotic telescopes, we believe that our project to install the telescope is feasible, and together with SAAO and others, to succeed in our mission.

In this presentation, we will describe in more detail what we outlined above.

The use of Oukaimeden Observatory remote observing facilities for training STEM and Education

Professor Abdelmajid BENHIDA

Faculty of Science and Technology Marrakech

Abstract

In Morocco, astronomy has seen remarkable growth over the past 30 years. The Oukaimeden Observatory (OUCA) in Morocco has made world-class discoveries and is leading various ongoing projects and collaborations, including many remote class telescopes for several thematics in Astrophysics.

Specific objectives of the OUCA include:

- contributions to repositioning Africa in the global production of knowledge in astronomy and space sciences by strengthening and expanding research expertise, and strengthening intra-African research collaborations.

- training of early career researchers and experienced researchers in astrophysics in Africa and Europe, through secondments and workshops.

- organization of observation campaigns with traditional and remote telescopes in Africa and worldwide. The OUCA provides the necessary human resources and knowledge exchange support to countries interested in developing observatories.

- promoting the scientific method for the general public and inclusion in science, technology, engineering and mathematics (STEM), through awareness and education events.

In Morocco, we focus on the ability and feasibility of building networks of remote/robotic telescopes for educational use at the undergraduate and high school level (recent years).

In this talk, I will describe :

-The plans that we have to develop at Oukaimeden remote/robotic observing facilities for the Universities (undergrad students) and High Schools pupils.

-Organization and management of the use of Oukaimeden Remote/robotic telescopes for educational purposes at the undergraduate and secondary level (last years)

-Plans to set up a collaboration with other African observatories and the creation of a network of remote/robotic telescopes users for this purpose.

Authentic research and scientific writing experiences using the LCO Telescope Network

Dr. Rachel Freed

University of North Carolina, Chapel Hill, USA. Institute for Student Astronomical Research

Abstract

The USA Sky Partners program provides research opportunities for undergraduate and high school students around the United States, using the Las Cumbres Observatory Global Telescope Network (LCO). Through this program, educators and students learn how to do double star astrometry on a double star system that they select. Using LCO they collect images of the system, make astrometric measurements of position angle and separation, and then share their results through writing a paper for publication in the Journal of Double Star Observations (JDSO). Our partners at the University of Puerto Rico, Occidental College in southern California, and the Institute for Student Astronomical Research (InStAR) have run the pilot program and students successfully published their research papers. Through InStAR, student and educator teams from 5 undergraduate institutions and 6 high schools around the United States participated in the program. Research on these astronomy research experiences has shown that students increase their self-efficacy and begin to develop a sense of science identity, both of which are important precursors to persistence within STEM fields.

[4]OAD National Astronomy Coordinator (NOC) GHANA,. [5]Ghana Space Science Technology Institutes. [6]African Astronomical Society. [7]NRA

Abstract

Astronomy holds immense potential for STEM education and public outreach development. In Africa, this potential remains largely untapped, with Ghana facing challenges in attracting students to STEM subjects and the public interents. Contemporary progress heavily relies on technologies used in astronomical techniques, data analysis from celestial bodies and satellites, and instrumentation processes, offering solutions to socio-economic issues like Decent Work and Economic Growth, particularly in developing nations like Ghana.

The AtroPhy project serves as a motivator for graduate and undergraduate students, acting as a gateway to astronomy and space science. It provides students with hands-on experience in radio telescope engineering and operational techniques, utilizing the Table Top Radio Telescope (TTRT) to observed the Galactic Hydrogen Emission (HI), process the data, and perform analysis using Python programming. The development of a small parabolic dish antenna into a radio telescope provides the participants with the skills of engineering and instrumentation in the field of astronomy and space science where a 2.4m parabolic satellite dish was converted into a radio telescope. These innovative tools, including the TTRT and small parabolic dish antenna set-ups, offer valuable learning opportunities in astronomy, space science, and data science, both for training and astronomy outreach communication. By fostering practical skills, nurturing scientific curiosity, and promoting collaboration, AtroPhy plays a pivotal role in addressing the UNSDG 4 and 8.

Finding Space for Observational Astronomy in the Secondary Science Curriculum

Ms Gerri Bernard

Brisbane Girls Grammar School

Abstract

In an effort to bring the awe and wonder of gorgeous astrophotography to all of our students, Brisbane Girls Grammar School has integrated observatory work into our Science curriculum. This presentation will explain how we use a series of 'Observatory Modules' in High School Years 7-9 to teach our students about the universe, telescopes, light, colour, CCD imaging, and image processing as we help them to generate more than 400 astrophotography images every year. The talk will also include an introduction to our school's remote and robotic telescope facility (the Dorothy Hill Observatory) and an overview of our school-based collaborative student astronomy research symposium (STARS), in which high school students are given the opportunity to complete astronomy research projects, contribute data to international variable star databases, and publish their research in peer-reviewed astronomy journals. In addition, an outline of struggles that we've encountered along the way and a plan for future outreach and development of our observational astronomy program will also be discussed.

Astrolab and its impact on the development of Astronomy teaching at the University of Zululand

Dr Getachew Mengistie, Prof Thulani Jili

University of Zululand

Abstract

The importance of using robotic telescopes that can be operated remotely in a STEM curriculum played a significant role in the understanding of the observational astronomy. It also improved students' ability to observe remotely, data acquisition and data analysis skills. The Astrolab project, one of the pioneering projects that uses the Las Cumbres Observatory (LCO) networked remotely controlled robotic telescopes, helped learners to understand observational astronomy and develop different skills. Moreover, it paved a way to observe from the comfort of their preferred places. It also introduces the learners to world class facilities. The University of Zululand in collaboration with OAD and DST took part in the Astrolab project and used it for learners to get background knowledge in astronomy and data analysis. The university is currently working on building an observatory which will house a 40-inch robotic telescope that can be used hand in hand with the Las Cumbres observatory. This robotic telescope will enhance the development of astronomy and is going to be used to train students at both the undergraduate and postgraduate levels. It is also aimed at training high school learners as a support instrument to those learners who are interested in astronomy as well as other STEM fields.

On-line Tutor Training for Astrolab, an astronomy lab with remote-robotic telescopes.

Dr Michele Gerbaldi[1], Prof, Dr Jean-Pierre De Greve[2], Dr Nicole van der Bliek[3]

[1]Institut d'Astrophysique de Paris, (IAP), France. [2]Vrije Universiteit Brussel (VUB), Belgium. [3]NSF's National Optical-Infrared Astronomy Research Laboratory (NOIRLab), Chile

Abstract

Astrolab is an enquiry-based astronomy lab allowing undergrad students to obtain hands-on experience with real astronomical observations. It follows the "Learning-by-doing" methodology: the students learn by experience, assimilating concepts through actions. Astrolab is geared towards undergraduate and graduate science students.

One can also use parts of Astrolab. For example, for a more technical, engineering course, one can focus on the properties of CCD images or on the optical properties of a telescope.

The Astrolab project supports universities with their observational astronomy classes, *at a low budget*, using remote telescopes.

The key of success of such hands-on activity is to make sure that the tutors themselves are trained, enabling them to optimally support the students.

We have developed a Tutorial on-line, *Astrolab Tutorial for Tutor Training*, on the Astrolab webpages. It guides you through the process of taking observations and analyzing the data.

It contains a comprehensive set of exercises to obtain a light curve of an eclipsing binary using the Las Cumbres Observatory 40-cm telescopes. For each step along the way, the Tutorial has an example and invites the user to carry out the activities themselves, including taking the data.

The tutorial also offers Tutors guidance on planning the implementation of Astrolab and on how to monitor progress of the student projects.

Our presentation will show the various aspects and goals of the Astrolab on-line Tutorial.

Empowering High School Students through Remote Asteroid Science Education: A Case Study of the Pan-Africa Asteroid Search Campaign

Dr Meryem Guennoun

Oukaïmeden observatory. Laboratory of High Energy Physics and Astrophysics

Abstract

This presentation delves into the intersection of remote education and asteroid science, with a special focus on high school students. Wearing the dual hats of a seasoned astrophysics researcher and a dedicated physics teacher, this exploration aims to showcase the symbiotic relationship between astrophysical research and effective science education. As one of the leaders of the Pan-Africa Asteroid Search Campaign, the talk will delve into the unique approach of virtually teaching high school and university students about asteroids. This includes hands-on experiences, such as using Astrometrica for potential asteroid discoveries. The study investigates the impact of remote teaching methods on fostering a profound understanding of space science among high school students, contributing significantly to the broader mission of advancing STEM education in virtual environments. The presentation aims to inspire the next generation by highlighting the dual role of a researcher and teacher in shaping the minds of budding space enthusiasts.

Robotic telescopes optimised for distance learners

Professor Ulrich Kolb

The Open University

Abstract

I will give an overview of the OpenScience Observatories (OSO), two robotic telescope facilities owned and operated by The Open University (UK), and describe their deployment in the OU undergraduate and postgraduate distance-learning curriculum, their wider educational use, and ongoing educational research on their effectiveness.

OSO consist of two fully autonomous robotic facilities located at the Observatorio del Teide (Canary Islands), PIRATE and COAST. The 60cm and 43cm astrographs are equipped with imaging cameras for multi-colour photometry, and they are part of a wider network of facilities that share a common control system.

OSO primarily serve the needs of OU distance learners in STEM disciplines, but they also support an active research programme in time-domain astrophysics and conduct commercial space situational awareness tasks. External providers of higher education can obtain access to the facilities.

In the formal OU curriculum the use of OSO is hierarchical and begins with real-time sessions and direct student control via a web interface to impart hands-on understanding of ground-based optical telescopes. For more advanced activities such as the monitoring of exoplanet transits for the ExoClock project or the follow-up of Gaia transients the observing requests are queue-scheduled. At the highest level OSO supports final-year Masters projects for an MPhys or MSc qualification.

We also offer an entry-level (pre-university) free online course, Astronomy with an online telescope, which is available worldwide and includes free access to COAST for deep-sky imaging and a citizen science-like activity on variable stars. Since 2019 over 14,000 learners have enrolled.

"Who Listens to the Radio" Remote Observing Programs in Radio Astronomy

Mr Robert Hollow, Dr George Hobbs

CSIRO, Space and Astronomy

Abstract

There are many excellent programs using remote and robotic optical facilities for astronomy education and training, but few utilising other parts of the spectrum. Since 2007, CSIRO's Space and Astronomy unit in Australia has run a successful program aimed at high school students in which they observe pulsars in real time, remotely, using Murriyang, the iconic 64m Parkes Radio Telescope. Our PULSE@Parkes program has engaged thousands of students across Australia and other countries. We discuss what we have learnt about how students interact with radio telescopes, the data and with our staff. The system's flexibility allowed us to pivot to online delivery during COVID 19 restrictions, replacing previous onsite sessions. We now offer both modes which allows schools across the country including regional and remote areas to participate. The model we have developed can be adapted by other institutions. The Victorian Space Science Education Centre, who have hosted many of our sessions, have themselves recently developed a program for remote observing using a 3m-diameter radio telescope. We discuss results obtained while exploring the market and possibilities for adapting the PULSE@Parkes model as a package for universities interested in training students in radio astronomy.

Participants will be able to remotely observe with Murriyang, the Parkes Radio Telescope and interact with the data in the first session.

[7]Space Telescope Science Institute, Baltimore, Maryland, USA

Abstract

The emergence of Covid-19 pandemic in 2020, created the need for a rapid response towards continuous research, despite the barrier created by quarantine and social distancing. In May 2020, the West African and Southern African Regional Offices of Astronomy for Development (WAROAD and SAROAD), Centre for Basic Space Science and Astronomy joined with GLAS Education and Stone Edge Observatory (SEO) to create and international partnership, aimed at providing a hands-on educational and research experience, through the use of SEO's remotely controlled 0.5m telescope in Sonoma, California. This project targets upcoming student scientists with interests in astronomy and planetary sciences. It provides them the opportunity to learn and develop the capacity required to independently identify potential observable targets of interest, plan observations and survey the sky from any part of the globe, with the help of their computer or mobile phones. The project aims to establish a legacy database of consistently and robustly reduced data with SEO and further perform time series analysis with the purpose of understanding the motion and properties of variable and transient objects in space. Within our framework, each student is equipped to remotely observe, download and stack images using Jupyter Notebooks, make plots, perform flux calibration and data reduction. Some preliminary results of our work on Stone Edge All-Sky Survey (SEASS), Asteroid photometry and study of M3 Globular Cluster (M3GC) are presented.

Sustainable Development of Astronomy Research Education in Sri Lanka with Remote Observations

Assistant Professor / Director of Communications Thilina Heenatigala

Earth-Life Science Institute (ELSI)

Abstract

Sri Lanka has produced about two dozen astronomers since the 1960s, and all graduated from foreign universities. Though students locally are keen on pursuing astronomy, as a developing country (not an IAU member), the opportunities and resources in astronomy are extremely limited. Since the days of the Apollo programme, there has been an active astronomy outreach at the school and public level, then led by the Ceylon Astronomical Association, which created a domino effect of school astronomy clubs, which are still active to date. A few decades later, the International Year of Astronomy in 2009 (IYA2009) boosted the outreach efforts, inspiring quite a few locals to pursue a career in astronomy despite the challenges. About a decade after the IYA2009, Sri Lankan astronomers focused on developing astronomy education and research at the university level. The first step was to partner with Las Cumbres Observatory (LCO) and get access to the telescope network. This partnership with LCO helped build the first active research group in Sri Lanka, which published the first scientific paper with all authors from Sri Lanka. Two universities are part of the research project where undergraduate students conduct remote observations and analysis to learn basic astronomy data analysis, tools, and techniques. The senior students are engaged in the research project as a credited course work which is a first in Sri Lanka.

This talk will present an overview of using remote observation for higher education in developing countries as a way to progress astronomy.

Robotic telescopes can change the trajectory of student's study and careers in STEM. Perspectives on the impacts and lessons learned from building a high school based remotely accessible observatory and how it has changed my own career trajectory.

Mr Andrew Yen

Luther College, Victoria, Australia. Eltham College, Victoria, Australia

Abstract

For forty years I have enjoyed bringing astronomy to young people through my involvement in astronomy associations and local schools. While I am passionate about astronomy, I've found it difficult to engage young people with the field. Access to reasonable telescopes, to allow continuation of the engagement pathway is an obvious hurdle. The telescope a youth can afford is likely to be disengaging rather than engaging.

Come to this talk to hear how this changed when I got involved with building a remotely accessible observatory (with a CDK17 and a RASA11) at my own children's school, Eltham College. This experience led to me returning to university to train as a teacher and a job as a Senior Physics teacher at another nearby school, Luther College. Luther College management were quickly convinced of the STEM teaching and engagement possibilities of robotic telescopes and have installed a 10" remotely accessible Newtonian.

I will present lessons learned and vital aspects to consider from the perspectives of a parent, an amateur astronomer, a physics teacher and a student on engaging middle and high school children, and the education institutions they attend, in education with robotic telescopes. Making real science, science where the youth gathers the data or takes the photo, engages young minds where pictures in books cannot. Giving youth the opportunity to take their science to professional level, continues the engagement pathway. In five years, I have helped students write journal papers on exoplanet followups, double star measurements, and discoveries of double stars.

The advantages of a remote telescope in Kenya for teaching purposes

Prof Colin Snodgrass[1], Cyrielle Opitom[1], Richard Vaughan[2], Melvin Hoare[3], Acacia Leakey[4], Edward Graham[5], Paul Baki[6], Susan Murabana[2], Dan Hillier[7]

[1]The University of Edinburgh. [2]Kenya Optical Telescope Initiative. [3]The University of Leeds. [4]Turkana Basin Institute. [5]University of the Highlands and Islands. [6]Technical University of Kenya. [7]United Kingdom Astronomy Technology Centre

Abstract

We will describe our work towards establishing a remote observatory in northern Kenya, in the context of its use for education. The Kenya Optical Telescope Initiative has been developing plans for an observatory in the remote, dark, and arid area of Kenya near lake Turkana, which is one of the few equatorial sites in the world that is well suited to optical astronomy. We installed a small telescope at the Turkana Basin Institute in 2022 to perform observations of the NASA DART mission's impact with an asteroid, and have subsequently used this for on site training of African students, which we will continue as part of the Development in Africa with Radio Astronomy programme in the coming years. In parallel we are performing site testing measurements on nearby mountain sites, which appear to be promising for a larger permanent and remotely controllable telescope. Such a telescope would be at an excellent longitude and latitude for university teaching in western Europe, with observations in the early evening after lectures but not requiring very late nights; daytime observing from the Americas; and provide a research and training facility for African astronomers.

GoChile telescope: A remote facility for secondary school and undergraduate students

Prof Andreja Gomboc, Dr Jure Japelj

University of Nova Gorica

Abstract

University of Nova Gorica (Slovenia) and astronomical magazine Spika run the GoChile project, which uses two small telescopes at the El Sauce Observatory in Chile. The two remotely operated telescopes are primarily intended for teaching—significant telescope time is reserved for secondary school and undergraduate students interested in astronomy. Through the project the students gain experience in observations and get introduced to the process of scientific research. I will present our activities in the past two years: remote teaching, mentoring of research projects and the organization of two summer schools. Interestingly, there has been a great interest in the telescope among girls, which was particularly evident in the summer schools, where more than half of the registrants and participants were girls. After two successful years of operation we intend to expand our activities and offer our facilities to other universities in need.

Educational Use of the North-West University 4-Element Radio Interferometer

Prof James Chibueze

University of South Africa

Abstract

North-West University 4-element radio interferometer consists of 4 identical 3.7m, fully steerable, prime focused, parabolic dishes. They are fitted with easily swappable C-band and L-band feeds. The array was designed to be a tool for hands-on radio interferometry education and for long-term monitoring observations of bright radio continuum and maser sources. Remote access to the interferometer is currently being explored and when rolled out, universities and colleges across South Africa and the rest of Africa will be able to access this facility for remote observations and education. As an educational instrument, the interferometer is already making significant impact in exposing students to hands-on radio telescope experiences. This talk will show some of the impacts of the practical experiences that students have already had with this instrument.

Lighting up the skies: How remote telescopes can enhance learning in the classroom

Dr Kshitij Thorat

University of Pretoria

Abstract

As Astronomy is at once possibly the most intangible and at the same time the most visible of sciences, teaching it in the classroom can be challenging. While looking up at the stars is free, delving deeper requires expensive telescopes. This is especially true in the Global South where access to telescopes is very scarce. In a way of contradiction, it is the Global as well as the Geographical South which is leading the way in professional astronomical studies, where large telescopes such as the South African MeerKAT, Australian ASKAP and Chilean Vera Rubin Telescope are based. To ensure that the future students in these countries are able to participate in a leading capacity in the exploration of our Universe using these wonderful facilities, it is imperative that their introduction to astronomy at school and undergraduate level is inspiring as well as complete.

Remotely operated and robotic telescopes can help in achieving these aims. In this talk, I will discuss the implementation of the IAU-OAD project “Astrolab” in undergraduate classrooms in the University of Pretoria. The project has students schedule observations and analyse the data of (primarily) transients using the Las Cumbres network of telescopes and is now a part of the second year astronomy course beginning in 2019. This has been for many students the first introduction to an astronomical telescope. I will further endeavor to bring to the fore student experiences with this experiment and alterations/additions which can be made to enhance astronomy learning in the classroom.

Remote telescope-based curricula for undergraduate introductory astronomy

Dr. Rachel Freed[1,2], Tiffany Stone-Wolbrecht[3]

[1]University of North Carolina, Chapel Hill. [2]Institute for Student Astronomical Research.
[3]Associated Universities Inc.

Abstract

Twenty-first century technology enables astronomy educators to offer our students unprecedented hands-on learning experiences. Two curricula, Our Place in Space! (OPIS!) and Multiwavelength Universe! (MWU!), have been developed for undergraduate astronomy which incorporate the use of the Skynet robotic telescope network. The advent of such telescope networks that enable remote collection of photometric, spectroscopic and even radio telescope observations as well as the proliferation of time domain and multiwavelength data from world-class facilities and advanced computing resources provide opportunities for students to learn and participate in modern astronomy, even at an introductory level. Within these curricula, students access remote telescopes and collect their own observations for analysis in activities aimed at teaching many of the major concepts in introductory astronomy courses in the United States. In conjunction with curriculum development, new analysis tools, Afterglow Access, have been and continue to be developed by the Skynet team. Using some of these tools students can contribute data to improve current catalog components, such as star cluster reddening and distance values.

Educational research has been carried out with several thousand students using these curricula and there has been a significant increase in self-efficacy relating to not only learning astronomy content, but also in technical skills revolving around using the telescopes. Furthermore, over the course of a single semester, the initial gender gap in self-efficacy disappeared as both men and women in the courses showed increased self-efficacy to the same levels.

Barriers to entry for high school (and university) education with robotic telescopes.

Dr Michael Fitzgerald

Las Cumbres Observatory

Abstract

It has been a long journey, really beginning in earnest around the early 1990s, towards connecting students with actual telescopes in everyday school environments. I myself hitched a ride on the school train around 2010 after about 5 years of university level robotic telescope education teaching experience.

We've come a long way… and to some extent we might even nearly …*nearly…* be there in terms of providing access and usage reliably to school (and university) users around the world over the next five years. And many of these things have been technical problems that have required technical solutions. But, try as hard as I might, I have yet to be able to code around human nature. We are rapidly coding our way through the technical barriers but we will always encounter numerous issues arising from our users being human and living in social, economic and occupational contexts in a universe more finite in time than in space. The issues at schools and universities actually are quite similar, but much more pronounced at the school level.

In this talk, I will provide the perspective of where we are at, what still needs to be done and what exciting new things that are rapidly appearing on the scene (with some quick handwaving towards history for context) across multiple projects and approaches. All of this presented in the gloomy atmosphere of why all this exciting stuff rarely, if ever, happens in normal classrooms and we can (perhaps) do to solve this.

[6]The Dill Faulkes Education Trust Limited, Great Britain. [7]Dept. of Physics, Univ. of Crete, Greece

Abstract

We report the results of LaSciL (Large Scientific Infrastructures enriching online and digital Learning - www.lascil.eu). This Erasmus+ project brought together five institutions from four countries (Austria, Greece, Portugal, UK) aiming to improve science teaching during and after the pandemic, focusing on modern science and astronomy. LaSciL addressed the increasingly prevalent access to 'big data in modern science, especially astronomy.

Teachers were presented with tools and resources curated and prepared by the partnership, allowing them to plan and perform astronomical observations using robotic telescopes from the Las Cumbres Global Observatory network. The toolkit consisted of 29 PDF guides to educational tools with significant online and digital components and 20 educational scenarios using these tools to apply in the classroom.

Teachers participated in two international schools where they developed their own educational scenarios suited to their needs and realities. The impact of the training on teachers and students was assessed, and a guide of good practices was created to support science teachers and propose a new framework for collaboration between schools and research infrastructures.

The teachers' feedback helped them understand the effectiveness of this approach and the kind of training that would be more helpful in their efforts. The project results were summarized in a guide of good practices to support science teachers and propose a new framework for collaboration between schools and research infrastructures. This presentation will conclude with an analysis of the project's impact on teachers and students one year after its ending.

Robotically Controlled Telescope at NOIRLab's Kitt Peak National Observatory: 25 years of supporting introductory astronomy education

Richard Gelderman

Western Kentucky University

Abstract

Astronomical research projects offer learners at all levels the chance to explore the process of science via hands-on experiences. New tools are required for today's learners - who have always had access through their smartphones to the global internet for factoids - to develop problem solving skills and to fully understand that science is a process, rather than a set of recorded results. The 1.3-m telescope at Kitt Peak National Observatory is operated as such a tool. Originally commissioned in 1964 as the "Remotely Controlled Telescope", a pioneering project in unattended, remote observing, the 1.3-m has been refurbished, automated and reborn as the "Robotically Controlled Telescope". This new incarnation of the RCT is used to pursue a variety of research programs which incorporate techniques to achieve extremely high precision photometric monitoring of stars, AGN, and other transient celestial phenomena, such as transits of extrasolar planets and follow-up observations of gamma-ray bursts. Our autonomous meter-class observatory enables unattended collection of deep, high resolution images, which are often combined with open access archival data to explore the full, multiwavelength nature of the targets. As a result, undergraduate and high school students work with the RCT to demonstrate their abilities with cutting-edge technology to make new discoveries.

Remote-controlled telescope as a tool for popularizing STEM subjects for high school students.

phd Michal Zejmo, phd Magdalena Szkudlarek, phd Waldemar Grabowski

Janusz Gil Institute of Astronomy, University of Zielona Gora, Poland

Abstract

We present the integration of remotely operated telescopes into the education of secondary school students, focusing on STEM disciplines. We examine the pedagogical implications and benefits of utilizing such advanced astronomical tools to enhance understanding and engagement in science, technology, engineering, and mathematics (STEM). Poster highlights the opportunities for hands-on learning, real-time observation, and data analysis that remote telescopes offer, fostering critical thinking and inquiry-based learning in STEM subjects. Moreover, it discusses practical strategies for incorporating remote telescope usage into STEM curricula, addressing challenges and maximizing educational impact. Overall, this poster underscores the potential of remote telescopes to inspire curiosity, deepen understanding, and cultivate STEM literacy among students at various educational levels.

Automation of the Dongla Observatory and Proposal to include it as a part of Global Network

Prof. Abhirup Datta[1], Dr. Anil Kothari[2]

[1]Department of Astronomy, Astrophysics and Space Engineering, Indian Institute of Technology Indore. [2]Madhya Pradesh Council of Science and Technology

Abstract

M.P. Council for Science and Technology (MPCST) has built the Varahamihir Astronomical Observatory situated at Dongla village. This Observatory has a 20" Telescope (Plane Wave CDK20 (OTA)) fixed with 5 meter (diameter) hemispherical steel structure dome at a height of 12.5 meters. Recently, we have started full dome automation work to make the telescope accessible from different institutions across the state of Madhya Pradesh as well as nationwide. Upon the completion of this automation work, Dongla Observatory will be accessible to the UG/PG students of different colleges across India. Dongla Observatory is based in Lat: 23◦26'43.2" Long: 75◦45'45.5" and was established back in 2013. We would like to discuss the potential of including this telescope in a global network of Sky-watch networks for locating transients, encouraging education in Astronomy and Astrophysics, and collaborative research

From Madagascar to the world: The Observatory of Ecoles du Monde de Madagascar and its potential for empowering STEM Education in resource-constrained regions

Mr Andoniaina Rajaonarivelo[1,2], Pr Sylvain Bouley[3], Pr David Baratoux[4], Ms Mializo Razanakoto[2]

[1]Astronomical Observatory of Ecoles du Monde Madagascar - Besely, Mahajanga, Madagascar. [2]Haikintana Astronomy Association, Madagascar. [3]GEOPS - Géosciences Paris Saclay, Université Paris Saclay. [4]Geosciences Environnement Toulouse, Université Toulouse III, CNRS & IRD, Toulouse, France,

Abstract

The Observatory of Ecoles du Monde de Madagascar (OE2M) stands as a groundbreaking initiative, being the first remote/robotic observatory established in Madagascar. This presentation explores the OE2M's potential to revolutionize STEM education for undergraduate and high school students not only in Madagascar but in resource-constrained regions, by fostering hands-on learning through:

- **Hands-on real-time astronomical observations** using the observatory's telescope.
- **Collaborative projects** : Students participate in international research initiatives, developing critical scientific skills like data analysis and communication while collaborating with researchers from various institutions.
- **Targeted training programs**: training programs equip students and amateur astronomers with the necessary skills to utilize the observatory effectively.

This presentation delves into:

- OE2M's unique capabilities and its future impact on STEM education in Madagascar and beyond.
- The broader potential of the observatory as a model for establishing similar facilities in other developing countries, promoting equitable access to scientific resources and empowering future generations of STEM professionals globally.

Keywords: Remote observatory, STEM education, Madagascar, Developing countries, Astronomy projects, Collaborative research, Training programs.

Outreach and engagement with autonomous telescopes: achievements and future plans

Sr. Carlos Gutierrez

Instituto de Astrofísica de Canarias. University of La Laguna

Abstract

This contribution highlights the successes of the Liverpool Telescope (LT) outreach programs and present the future of our engagement plans with the LT's partner, the New Robotic Telescope (NRT).

Since 2004, the LT has dedicated a considerable amount of observing time to educational and astronomy outreach programs aimed at students, teachers and amateur astronomers in the UK, Spain and other countries through The Schools' Observatory (TSO) and PETeR (The Educational Project with Robotic Telescopes). These programs allow that 1,200 teachers and their students each year develop an inquiry project by taking and analyzing their own astronomical images through an online platform designed to be accessible and easy to use.

The NRT, the 4m sibling of the LT, will provide autonomous, rapid optical observations of transient phenomena in the northern hemisphere sky. Set to come online in the late 2020s, the NRT is an innovative and challenging project that brings together astronomy and engineering to build a unique and flexible system of many complex parts. The NRT project is focusing its outreach efforts on showcasing the variety of skills of the team members, along with the adaptability and scope of people with science and engineering degrees. Through collaborations with TSO and PETeR, the NRT will host a range of STEM-focused careers activities on their website, designed to highlight exciting prospects and educate school-age children about the range of roles available within science and engineering; particularly within a project environment.

Observing Experiences for Undergraduate Students with the Skynet Robotic Telescope Network

Megan Dubay, Dr. Daniel Reichart, Joshua Haislip, Vladimir Koupiranov, Reed Fu

University of North Carolina at Chapel Hill

Abstract

The Skynet Robotic Telescope Network ("Skynet") consists of 20+ fully automated, professional-grade optical and radio telescopes at various sites around the world. Skynet is a global network of robotic telescopes and sophisticated web-based software that can control most commercially available hardware and provide users with straightforward observation scheduling. The Skynet mission includes both research and education initiatives. Research interests vary from near-Earth objects to supernovae and gamma-ray bursts. On average, Skynet data appears in peer-reviewed publications every 24 days.

We developed introductory astronomy undergraduate curricula over the past 16 years that leverage Skynet to allow for hands-on learning using professional instrumentation. Afterglow Access and Astromancer graphing, analysis, and modeling tools are in development to further advance opportunities for students to do the same science that required advanced knowledge just a few years ago. These curricula, *Our Place in Space! ("OPIS!")* and *Astrophotography of the Multi-Wavelength Universe! ("MWU!")* focus on teaching students how to do the science they learn about in their classes for themselves, and see how the practice of astronomy works. Multi-million dollar grants from NSF and DoD STEM are being used for development, expansion, and education research of these curricula. OPIS! focuses on a cosmic distance ladder approach, and has been expanded to serve ~1.5% of all introductory astronomy students in the US. MWU! uses astrophotography as a hook for the color-based exploration of stellar and galactic formation and evolution.

STEM education with robotic telescopes: lessons from the PETeR project

Nayra Rodríguez-Eugenio, Alejandra Goded Merino

Instituto de Astrofísica de Canarias (IAC)

Abstract

The *Instituto de Astrofísica de Canarias* (IAC) is a Spanish astrophysics R&D centre that operates the Canary Islands Observatories, which house the telescopes of some 60 institutions from more than 20 countries. The IAC and the owner institutions sign cooperation agreements whereby Spain receives a percentage of the observing time on each telescope. In 2004, the IAC decided to allocate part of its guaranteed time on some robotic telescopes to education and created the Educational Project with Robotic Telescopes (PETeR), an online inquiry-based laboratory that allows schools to carry out their own observations and research projects in astronomy. Access to several telescopes, which also offer different types of observations through user-friendly portals, has allowed us to open the project to the entire Spanish educational community, from primary to secondary schools. Currently, some 450 schools are PETeR users.

All our users have access to the variety of resources and educational approaches we offer: predefined observations of selected objects, activities and research projects with previously observed data, guided research projects and open astronomical investigations, using both automatic and remote-controlled observations. This makes PETeR a unique laboratory to assess the suitability of each of these models to the type of user, as well as their strengths and weaknesses.

In this talk we will review the advantages and disadvantages that we have identified of each approach, the type of user that prefers each of them, as well as the resources, training and support that users require to be able to develop them effectively.

Skynet Astromancer and Astronomicon: designing a suite of tools to facilitate course-based research with robotic telescopes at the introductory level

Daryl Janzen[1], Ruide Fu[2], Mandela Fraser[1], Daniel Reichart[2], Joshua Haislip[2], Vladimir Kouprianov[2], Megan Dubay[2], Kalee Tock[3]

[1]University of Saskatchewan. [2]University of North Carolina at Chapel Hill. [3]Stanford Online High School

Abstract

Technological advances over the past two decades have enabled us to develop global networks of research-grade robotic telescopes with image reduction pipelines that give introductory astronomy students access to photometric data collection across the entire night sky. For the educator, this opportunity comes with a challenge, to design projects with data reduction and analysis procedures, and avenues to publish the results of these research projects, that are similarly accessible to our students. To this end, we will provide an overview of the tools available through Skynet's web-based data processing, analysis and catalogue suites. In particular, this talk will focus on the tools we've created to enable large introductory classes to study star clusters—from observation to colour image processing, automated source extraction and photometry, to field star removal and isochrone modelling, to results publication in an updatable catalogue. Challenges and open issues associated with building and maintaining this suite of tools will be discussed along with plans for next steps.

Training of astronomy club leaders in Senegal : ORION Astro Lab project

PhD Salma Sylla

Université Cheikh Anta Diop

Abstract

Here we present our experience in training astronomy club leaders in Senegal. Over the past six years, Senegal has been the scene of major astronomy activities such as NASA's three occultation space missions in 2018, 2020 and 2022, online and/or face-to-face training workshops thanks to various facilities such as Office of Astronomy for Development and Office of Astronomy for Outreach funding, and collaborations between various local and international structures. ORION Astro Lab program is one of these initiatives. This program was developed in collaboration with Madagascar. With the support of the Office of Astronomy for outreach, this project has trained twenty (20) astronomy club leaders in Senegal.

Teaching astronomy with ASTROLAB, a Peruvian experience

Dr Myriam Pajuelo[1], Aldo Panfichi Sanborn[1], Dr Nicole van der Bliek[2]

[1]Pontificia Universidad Catolica del Peru. [2]NSF's NOIRLab

Abstract

We present our experience teaching an introductory astronomy course at the Pontifical Catholic University of Peru (PUCP). Students both attend theoretical sessions and participate in practical experiences. The course uses the ASTROLAB (Starlight in the university laboratory) tutorial, developed by Michele Gerbaldi and Jean-Pierre De Greve. Astrolab is a project of the Office of Astronomy for Development (OAD) of the IAU. There is a need to have access to telescopes and instruments to perform practical work - in this sense, remote/robotic telescopes are a very good option given the few opportunities that Peruvian undergraduate students have to do observational astronomy, and also due to the fact that the few astronomical facilities that exist in the country are far from the university.

The students are introduced to scientific research methods as they go through the same steps astronomers take when preparing and carrying out an observing program. Alongside these sessions, students enthusiastically learn how to plan observations, submit proposals, process their data, and analyze their results; having access to professional software and query of database (Gaia, CDS, etc) and Virtual Observatory (VO) tools on images obtained from remote telescopes in professional observatories from Las Cumbres Observatory 40 cm telescopes. This teaches students to develop teamwork abilities, understand the complexity and ambiguity of empirical work, develop practical skills, error analysis, defend their results both in written and oral form, and most importantly: develop critical thinking.

The use of robotic telescopes in astronomy and physical sciences classes at university level in Puerto Rico

Dr. Mayra Lebron[1], Dr. Carmen Pantoja[1], Dr. Lisa Storrie-Lombardi[2], Dr. Edward Gomez[2], Dr. Rachel Freed[3], Dr. Sabrina Stierwalt[4]

[1]University of Puerto Rico - Río Piedras Campus. [2]Las Cumbres Observatory. [3]InStAR. [4]Occidental College

Abstract

The USA Sky Partner is a pilot program, adapted from the Astronomy Research Seminar of INStar, funded by the National Science Foundation Partnerships in Astronomy & Astrophysics Research and Education (PAARE) program. USA Sky Partners allows undergraduate students to learn about science through an astronomy research project of double stars. The participating students work on most parts of a research process including the use of the 0.4m robotic telescopes of Las Cumbres Observatory for the observations, data analysis, result dissemination and peer review paper publication. The Río Piedras Campus of the University of Puerto Rico (UPR-RP) is part of this pilot program. At UPR-RP we have implemented the experience as part of a general astronomy course (ASTR3005) and a general studies science course (CIFI4005), with the participation of 47 undergraduate students. This research experience resulted in 4 articles submitted to the Journal of Double Star Observations (two have been accepted and two are under revision) and four student presentations at local undergraduate research conferences and one presentation at the American Astronomical Society meeting. In this work we present the experience, benefits and challenges during the implementation of the USA Sky Partner project in the courses ASTR3005 and CIFI4005 at UPR-Río Piedras.

Correlating IceCube-170922A Neutrino Event with γ-Ray Spectrum from TXS 0506+056 using *Fermi*/LAT Data

Mr. Rajendra Neupane[1,2], Dr. Niraj Dhital[1]

[1]Central Department of Physics, Kirtipur, Kathmandu, Nepal. [2]Birendra Multiple Campus, Bharatpur, Chitwan, Nepal

Abstract

We conducted an analysis of γ-ray data of TXS 0506+056 detected by *Fermi* LAT spanning from August 13, 2010, to August 12, 2023. We generated a comprehensive light curve covering the entire thirteen-years period. Through this analysis, we identified potential flaring events within the data and the correlation of the IceCube-170922A neutrino event with the flaring. In 30-day time intervals, we determined energy flux, photon flux, and spectral index. The spectral index was at its lowest value of 2.003 ± 0.057, and the energy flux was at (1.945 ± 0.211) × 10^{-4} MeV cm−2 s^{-1} during the time frame when the IceCube-170922A neutrino event was detected. This indicates a significant flattening/hardening of the spectrum during the detection of the IceCube-170922A neutrino event. There is no correlation between the highest flux state and the high energy IceCube-170922A neutrino event detected on September 22, 2017 because the highest energy flux of (3.329 ± 0.452) × 10^{-4} MeV cm−2 s^{-1} was obtained during the period between June 28, 2017, and July 27, 2017.

JASMINE: near-infrared space astrometry mission

Professor Naoteru Gouda[1], JASMINE team[2]

[1]National Astronomical Observatory of Japan. [2]ISAS/JAXA, NAOJ and other institutes

Abstract

JASMINE is a satellite mission to perform infrared astrometric observations in the direction of the Galactic nuclear region. JASMINE was selected by ISAS/JAXA (Institute of Space and Astronautical Science/the Japan Aerospace Exploration Agency) for the JAXA Competitive Middle-Class Science Missions No.3. This mission is unique in that the same astronomical object can be observed frequently, and observations will be performed in the near-infrared band, in which the effect of absorption by dust is weak. JASMINE uses an infrared camera under development in Japan to observe in the Hw band of wavelengths from 1.0 microns to 1.6 microns. JASMINE will determine parallaxes (proper motions) accurate to between 25 μas （25μas/y) and 125 μas (125μas/y), depending mainly on the star magnitude. This mission will help to achieve revolutionary breakthroughs in astronomy and astrophysics, including the formation history of the Galactic nuclear structures (Galactic Center Archeology) and the supermassive black hole at the Galactic Center etc. In terms of understanding our Galaxy's structure, and its formation and evolution, the Galactic nuclear region is particularly important region because stars of various ages have different spatial distributions and motions according to their ages in this region although this region covers only a small part of the sky. It's like having different strata in geology. JASMINE will also be useful for exploring dark matter, black holes, X-ray binary star systems, and stellar clusters, in the inner region along the Galactic plane. The brief overview and recent progress of the JASMINE mission will be explained.

STEP II: Precision Narrow-Angle Space Astrometry in Orbit

PhD Ding Chen[1], Fei Huang[2], Heqing Wang[2], Zhuoer Shao[3]

[1]Shanghai Aerospace and Space Technology. [2]Shanghai Aerospace Control Technology Institute. [3]Cornell University

Abstract

Search for Terrestrial Exo-Planets (STEP) mission aims at the Micro-arcsecond Narrow Angle Space Astrometry, which offers a unique astronomical instrument for the astronomers and the planet scientists to start a new view on the research. After the success of the Pathfinder mission (STEP I) in orbit in the past two years, we started a medium science mission STEP II, going to be launched soon this year, which will provide a special Narrow-Angle Space Astrometry tool for the Astronomers worldwide to use and will be a good complementation to the wide-angle global survey astrometry mission such as the noted Gaia mission. The primary scientific purposes of this mission will be the precision astrometry on the nearby Stellars and the Exo-planets detection. The overall design and the detail info. of the mission will be introduced in this talk. The additional suggested targets, interesting scientific goals, observation proposal, collaborations or special Astronomical scientific purposes are welcome!

NEW ASTROMETRIC SOLUTION AUS2024A BY GEOSCIENCE AUSTRALIA

Dr Oleg Titov[1], Dr Simon Willcocks[1], Dr Yulia Lopez[2], Ms Angelina Osetrova[3]

[1]Geoscience Australia. [2]University of Tasmania. [3]Saint-Petesburg State University

Abstract

Herewith we present a new Celestial Reference Frame (CRF) solution produced by Geoscience Australia (aus2024a.crf). A 30-year set of geodetic VLBI observations was processed with self-calibration of the wet troposphere delay and gradients along with reference clock offset variations. The formal accuracy of all astrometric parameters is improved by a factor of three with respect to the standard solution. We analyzed more than 15 million group delays and provided high precision coordinates of 5428 radio sources with the best formal positional error of about 2 μas. Additionally, the negative parallax effect with an amplitude of -15.8 +/- 0.5 μas was detected. Independent estimate of this effect by the Gaia optical mission (EDR3 release) is -17 μas, i.e. the estimates from the two independent techniques are consistent. We tend to think that the negative parallax effect could be caused by a real physical reason rather than instrumental problems. More investigation is required to develop a plausible explanation of the detected effect.

Progress Towards ICRF4 at X/S and K Bands

Dr. David Gordon[1], Dr. Aletha de Witt[2], Christopher Jacobs[3], Dr. Hana Krásná[4]

[1]U.S. Naval Observatory. [2]South African Radio Astronomy Observatory. [3]Jet Propulsion Laboratory, California Institute of Technology. [4]Technische Universität Wien

Abstract

ICRF4 is scheduled to be submitted to the IAU for approval at the 2027 IAU General Assembly in Rome. This report will summarize the progress made towards expanding and improving the ICRF at X/S and K bands during the 5 years since ICRF3 was generated. The current X/S band CRF now consists of over 5700 sources constructed from more than 18 million VLBI observations using over 7100 VLBI sessions taken over a 43 year period. The distribution of sources north of -45° declination is fairly uniform, with some over-density near the ecliptic plane to provide more sources for spacecraft navigation. The X/S sources in this part of the sky are dominated by VLBA observations. South of -45° declination, the density of sources is much lower due to fewer observations from fewer and less sensitive antennas in the southern hemisphere. The K band CRF now has over 1300 sources from 161 K band sessions with over 2.5 million observations from 2002-2024. K band sessions have been made with the VLBA, the HARTRAO-HOBART26 network, the HARTRAO-YEBES40m network, and the Korean VLBI network (KVN) with HARTRAO, YEBES40M, SEJONG and MOPRA. The distribution of K band sources is fairly uniform between both hemispheres, however position uncertainties increase rapidly in right ascension south of -40° and in declination south of -10°. Efforts are underway to improve the southern precision by getting more observations to HARTRAO, HOBART26 and MOPRA.

X/S versus K Band Source Stabilities from Time Series Analysis

Dr. David Gordon, Dr. Phil Cigan, Dr. Christopher Dieck

U.S. Naval Observatory

Abstract

It has commonly been assumed that quasar positions should be more stable at higher radio frequencies. But is this correct? We investigate this question by comparing VLBI time series source positions at X/S and K bands for several hundred sources. At X/S band, we use time series solutions from VLBA, RDV, R1 and R4 sessions from 2016-2024. At K band we use VLBA astrometry sessions, also from 2016-2024. Comparisons of the data show slightly less scatter for K band in right ascension, but greater scatter in declination, presumably due to the smaller north-south extent of the VLBA and accompanying larger declination uncertainties.

The statistics of Gamma-Ray Burst redshifts

Istvan I. Racz[1], Istvan Horvath[1], Zsolt Bagoly[1,2]

[1]University of Public Services. [2]Dept. of Physics of Complex Systems, Eötvös University

Abstract

An extensive analysis using almost 600 precise distance measurements of gamma-ray bursts (GRBs) was conducted. Unfortunately, an observed trend indicates a decline in the number of redshift measurements associated with GRB sightings. While previous studies have revealed significant cosmic structures leveraging GRB data, a more comprehensive understanding necessitates an increased spatial distribution of GRB observations to investigate their relationship with conventional cosmological structures. To address this gap, we examined the distribution of known GRB distances with the aim of estimating distances for GRBs lacking redshift measurements. We propose a potential methodology for calculating distances to Swift GRBs based on observed parameter values.

Optical/IR interferometric astrometry: the key diagnostic when understanding complex massive binary systems

Dr Abigail Frost

European Southern Observatory (ESO)

Abstract

Massive stars (those greater than 8 solar masses) are hugely important objects in our Universe. They synthesise heavy elements through and produce huge amounts of ionising radiation and distribute this into the interstellar medium. Their winds shape their local star forming regions and also affect the morphology of galactic superwinds (Leitherer 1994). Additionally, gravitational waves are the end product of massive stellar mergers, with black holes and neutron stars colliding to create ripples that are felt across the galaxy (Abbot et al 2016). The effects of a massive star can be irrevocably changed by their multiplicity. At least 90% of massive stars are expected to be in at least a binary system (e.g. Moe & di Stefano 2017) and 70% of these stars are expected to interact with eachother (e.g. Sana+ 2012). In this talk I will discuss how astrometry, particularly from spectrointerferometry with the VLTI, is now proving invaluable in the study of complicated massive binary systems. Through the presentation of two case studies, I will describe how the precise data of VLTI/GRAVITY is allowing us to break degeneracies when characterising orbits, attribute spectral features to specific stars and in doing so allow us to definitively identify massive stellar systems that have gone through interactions (e.g. Frost 2022) and even main sequence merger events (Frost 2024, in press).

Towards ephemerides of ICRF quasars

Dr. Valeri Makarov

U.S. Naval Observatory

Abstract

ICRF quasars are not stationary radio sources on the sky. Their positions change in time along complex jittery trajectories, that are quite obvious in precision geodetic VLBI measurements separated by day of observation. The contribution of this intrinsic instability is best seen for the radio-bright sources, which tend to be defining and most frequently observed, where it becomes up to a factor of 3 greater than the formal error of astrometric measurement. These epoch-dependent variations, which we call "cosmic error" in analogy with astrometric binaries, have adverse effect on the main applications of ICRF, such as UT1-UTC monitoring and Earth orientation parameters determination. We investigate the properties of this effect in the statistical sense and quantify the impact on the Maximum Likelihood mean positions and proper motions for the general ICRF3 sample.

TOWARDS CORRECTING SOURCE STRUCTURE FOR AN IMPROVED K-BAND (24 GHz) CELESTIAL REFERENCE FRAME.

Namakau Shirac Mwiya[1], Aletha de Witt[2], Christopher Jacobs[3], Hana Krásná[4], Michael Bietenholz[2], Marisa Nickola[2], Megan Johnson[5]

[1]University of Pretoria. [2]SARAO. [3]Jet Propulsion Laboratory, California Institute of Technology. [4]TUWien. [5]USNO

Abstract

The AGN that define the radio Celestial Reference Frame (CRF) are not perfect stable point sources and are known to vary in both flux density and structure on timescales of months to years. The variations in structure can lead to significant errors in astrometric Very Long Baseline Interferometry (VLBI) measurements. Ideally, the effects of source structure should be accounted for in the VLBI analysis, but such modelling requires an ongoing imaging effort for all CRF sources. Observing at 24 GHz, higher than the traditional-used frequencies below 10 GHz, allows for better resolution and astrometric accuracy.

Using a systematic compilation of 24 GHz VLBI images, we extracted image properties and studied the source compactness in order to comprehensively characterize the structural attributes of targeted sources. Fourier transform, variance analysis, and correlation studies were employed to assess the sources' temporal stability and specifically investigate the correlation between VLBI astrometric position offsets and source structure. Through this analysis, we sought to precisely quantify the impact of source structure on observations at 24 GHz. This quantitative analysis will inform the development of a corrective model tailored for addressing source structural effects. Subsequently, this model will be integrated into existing VLBI analysis software, enhancing its capability to account for and mitigate the influence of source structure on observations.

VGOS CRF 2024a: using radio multiband data to create a CRF for geodesy

Hana Krasna[1], Christopher Jacobs[2]

[1]Technische Universität Wien (TU Wien), Austria. [2]Jet Propulsion Laboratory, California Institute of Technology, USA

Abstract

The next generation Very Long Baseline Interferometry (VLBI) Global Observing System (VGOS) for geodesy and astrometry simultaneously observes the active galactic nuclei in four radio bands, ranging from 3 to 11 GHz. The goal of VGOS is to improve the accuracy of geodetic and astrometric data products, such as the Earth orientation parameters or the terrestrial and celestial reference frames. We present the celestial reference frame (CRF) estimated from group delays coming from VGOS Operational (VGOS-OPS) and Research and Development (VGOS-RD) 24-hour sessions. The first five test sessions were conducted in December 2017, followed by regular VGOS-OPS sessions starting in January 2019 with a two-weekly cadence.

The VGOS CRF 2024a comprises over 400 radio sources, with the majority located at declinations higher than -45 degrees. This is due to the CRF being computed using observations from 13 antennas, of which only two (Hobart12 and Kath12m) are located in the southern hemisphere. We show the comparison to ICRF3-SX and to Gaia optical celestial frame. Solving for just 3-D rotations, the arc-differences vs. arc-length show agreement with ICRF3-SX to 10 microas, if in addition to the usual no-net-rotation constraint also the delta declination vs. declination slope is constrained. The further improvement of the VGOS CRF depends mainly on building more VGOS telescopes in the southern hemisphere. This will further lower the formal precision in declination of the southern radio sources and it will improve the global distribution of the sources included in the VGOS frame.

Status of the Q-band CRF in 2024 and roadmap forward: extending the CRF to higher radio frequencies

Hana Krasna[1], Christopher Jacobs[2], Aletha de Witt[3], Frederic Jaron[1], David Gordon[4], Taehyun Jung[5]

[1]Technische Universität Wien (TU Wien), Austria. [2]Jet Propulsion Laboratory, California Institute of Technology, USA. [3]South African Radio Astronomy Observatory (SARAO), South Africa. [4]U.S. Naval Observatory (USNO), USA. [5]Korea Astronomy and Space Science Institute (KASI), Korea

Abstract

We present a preliminary Q-band (43 GHz) CRF catalog, built from three 24-h Very Long Baseline Array (VLBA) sessions observed as part of an imaging comparison campaign. Nearly simultaneous VLBA sessions in S, X, K and Q-band were organized monthly from April to June 2021, observing radio sources from the same list. This Q-band CRF consists of more than 400 radio sources and their 67 thousand group delay observations. The median formal precisions are about 200 microas in right ascension and about 350 microas in declination. The global agreement with the ICRF3-SX and the Gaia optical celestial frame is at the level of 1.5 parts per billion. The motivation to explore the ability of radio observations of extragalactic sources at 43 GHz to build the CRF, is mainly the reduction of plasma distortion of the signal and the more compact morphology of most of the sources compared to lower frequencies. The prospects for future improvements are bright, covering the potential to add Q-band VLBI observations using the Korean tri-band (K, Q, W-band) system; exploring the southern baseline observations between Mopra, Australia and CART 40m, Argentina; and proposing more Q-band time on the VLBA with the planned upgrade from 4 to 8 Gbps data rates. We acknowledge that the VLBA time is being sponsored under the USNO time allocation.

The infrared reference frame in Gaia era based on AllWISE and CatWISE catalogs

Dr. Jia-Cheng Liu

Nanjing University

Abstract

The launch of Gaia in December 2013 ushered in a new era of space astrometry, allowing for fundamental reference research at an unprecedented level of precision. The international celestial reference frames (ICRF) in radio band and the Gaia celestial reference frame (Gaia-CRF) in optical band have been established and are consistent within several micro-arcseconds for axes orientation. To bridge the gap between the visual and radio bands, an infrared reference frame should be investigated. We present a study aimed at constructing an infrared reference frame using the observations from the AllWISE and more recent CatWISE catalog. After cross matching with Gaia DR3, systematic differences in positions and proper motions, such as magnitude or color equations and vector spherical harmonics are derived. These systematic differences are comparable to the random errors in the infrared astrometry and can be used to improve the source positions and proper motions, making the AllWISE or CatWISE catalog a valuable extension of the all-sky reference frame in the infrared band. Our investigation reveals that extragalactic sources and stars in the infrared catalogs exhibit different astrometric properties. The global difference between the extragalactic source reference frame and the stellar reference frames is found to be about several mas for global rotation and glide amplitudes, respectively. Such internal inconsistency should be mentioned when exending the Gaia stellar reference frame to longer wavelength.

Extragalactic radio and optic fundamental astrometry

Leonid Petrov

NASA Goddard Space Flight Center

Abstract

A lot of efforts were put into running dedicated absolute astrometry VLBI campaigns during last three decades. Analysis of data collected in these campaigns allowed us to produce a catalogue of radio source positions of over twenty thousands of active galactic nuclei (AGN) with nanoradian accuracies. Analysis of the ongoing space astrometry Gaia mission resulted in a catalogue of over one million AGNs with comparable accuracies. Radio and optic astrometry has a lot of common features, but also has certain distinctions. Analysis of these commonalities and differences will be presented. When commonalities in two astrometric catalogues can be used for strengthening positional astrometry and what are limits in combining two catalogues will be discussed.

The masses of Milky Way globular clusters using GAIA data.

Jane Letsoalo[1], Dr Bruno Letarte[1], Dr Zolile Mguda[2]

[1]North-West University. [2]UNISA

Abstract

Globular clusters, dense groups of stars formed from a common molecular cloud, offer valuable insights into star formation as they exhibit similar chemical composition, age, and kinematics. Serving as natural laboratories, they enable the study of fundamental parameters such as distances, ages, metallicities, sizes, and masses.

This study employs the Leonard-Merritt method to measure the masses of the ten nearest globular clusters. The mass distribution is modelled by fitting the photometric characteristics of each globular cluster to the King model. The gravitational potential is determined using proper motion data from the Gaia space telescope, leveraging precise astrometric measurements for accurate proper motion throughout the galaxy. The Gaia mission's high-precision astrometry facilitates mass measurements for numerous globular clusters using a unified dataset and a single measurement technique. This study establishes a robust reference point for the Leonard-Merritt technique by comparing its results against the literature masses of the selected globular clusters. The comprehensive approach ensures accurate and reliable mass determinations, contributing to our understanding of globular cluster dynamics and their role as crucial astronomical laboratories.

Accurate VLBI astrometry and strong lensing as a direct test to the LambdaCDM model

Dr. Cristiana Spingola

INAF Institute for Radioastronomy

Abstract

Accurate astrometry of strong lensing systems can address fundamental open questions in cosmology. In particular, the micro-arsec astrometric accuracy achievable with Very Long Baseline Interferometry (VLBI) can infer the nature of dark matter, as it allows to directly detect at high significance the milliarcsec-level gravitational effect of the (expected) sub-halos on the lensed images. Our results on the astrometry of VLBI-observed gravitational arcs can constrain the dark matter particle mass at the same level of the number statistics of the satellites of our Galaxy and demonstrate the power of the method, anticipating what SKA-VLBI will be able to reveal.
Strong lensing also provides a magnified view of distant background sources, which cannot be detected and spatially resolved with current instruments. With a multi-band dataset that includes VLBI, HST and Chandra observations, we started a systematic astrometric analysis to search for offset and dual AGN at high-z. Our results reveal multi-band offsets on hundreds of parsecs in sources at $z > 1$ and we found a dual AGN candidate that, if confirmed, implies an order of magnitude mismatch between the observed and predicted dual AGN systems.
Accurate astrometry is also important for finding strong lenses. I will discuss our effort in developing efficient methods to find lenses using wide-field radio surveys, in preparation for the SKA1-MID surveys that will reveal 10^5 strong lenses.

ngVLA for VLBI in the 2030's and beyond

Dr Megan Johnson[1], Dr David Gordon[1], Dr Phil Cigan[1], Dr Lucas Hunt[2]

[1]US Naval Observatory. [2]National Radio Astronomy Observatory

Abstract

The next generation Very Large Array (ngVLA) is proposed for the 2030's timeframe and if approved, will include long baselines to replace the current Very Long Baseline Array (VLBA). We present an overview of the goals for the ngVLA long baselines for supporting scientific topics including, compact object research, stellar imaging, extrasolar planetary systems, fast radio bursts, pulsars, and fundamental astrometry including the International Celestial Reference Frame (ICRF) in the 2030's and beyond. The breadth of science that the ngVLA long baselines will provide will inevitably change our views of the Universe. One of the areas we plan to contribute most is in the maintenance and improvements of the ICRF. Integrating and sustaining a multi-wavelength ICRF will be challenging in the coming decades. We explore some of these challenges related to very long baseline interferometry (VLBI) and discuss how ngVLA might be realized to support these ambitions. We will also present some recent results towards this effort from data collected on the VLBA and showcase the USNO Fundamental Reference Image Data Archive (FRIDA), a repository of ICRF multi-frequency radio images.

Ultra-Precise relative Astrometry with next-generation VLBI: Methods, Opportunities and Requirements

Dr Maria J. Rioja[1,2], Dr Richard Dodson[1]

[1]ICRAR-UWA. [2]OAN-IGN

Abstract

We are at the cusp of a generational shift in the power of radio interferometers, with exciting next-generation instruments, such as SKA, ngVLA and upgraded EHT, that are coming online. Next-generation VLBI observations bring a potential order-of-magnitude improvements in sensitivity and in astrometric performance, provided that the requirements for optimum calibration methods and usability are not designed out. We have been exploring the implications for astrometry of these new instruments, as sensitivity alone will not improve over the current astrometric limits - being systematic and not driven by thermal noise. Thus using traditional phase-referencing techniques will not be able to significantly overcome the current astrometric accuracy nor extend the moderate range of operational frequencies.

The developments that drive forward the field of ultra-precise astrometry constitute a very active field of research. Next-generation methods such as *Source-Frequency-Phase-Referencing* and/or *MultiView*, combined with next-generation technology, offer an order-of-magnitude increase both in accuracy and in the range of operating frequencies across the radio spectrum, for both ground and space-VLBI domains. In this talk I will report on the fundamentals, potential and recent on-going steps to confirm that these new methods will deliver on their promise and to ensure that any technological requirements are not designed out from the next-generation instruments. We foresee that the combination of the next-generation developments (on instruments, methods and technology) will have the greatest impact in the compilation of large and unbiased ultra-precise astrometric surveys, compared to current instruments, expanding the role of VLBI into new areas of research.

Prospects for sub-mm astrometry with the ngEHT

Dr Richard Dodson[1], Dr Maria J. Rioja[1,2]

[1]ICRAR/UWA. [2]OAN/IGN

Abstract

Astrometry at the very highest of frequencies is an unexplored frontier for VLBI observations. Astrometry is vital to connect observations at different times and different frequencies. The former is used for measuring proper motions and parallaxes to derive distances to the targets - and thus their physical characteristics. The latter is to reference two images at different frequencies together, which is equally important. No spectral index or rotation measure is valid if the observations are not registered.

One of the exciting new facilities that will be available in the near term is the next generation Event Horizon Telescope. This has recently been extended so that multiple frequencies will be observed simultaneously; 86-, 230- and 340-GHz. Multi-frequency observations result in a transformational boost in the capabilities of the ngEHT, providing the vital phase referenced registration between frequencies.

We will describe how this new capability will allow ultra-precise bona-fide astrometric studies, based on simulations. We will report on our first attempts to apply frequency phase transfer at mm-wavelengths. In addition we will discuss MultiView astrometry, which was designed for `lower' frequencies, but we are also pushing it towards mm-wavelengths, with observations at 43GHz and proposals for 86GHz. The combination of these techniques would offer all varities of astrometric measurements at these extreme frequencies, and thus investigations of the most extreme of physical conditions.

Astrometry of Variable Stars in Clusters

Prof. Alisher S. Hojaev

Ulugh Beg Astronomical Institute

Abstract

The search and study of variable stars in star clusters and associations is of interest not only for studying the nature of their variability, but also for understanding the physics, kinematics and evolutionary characteristics of these groups of stars themselves. We present current results of long-term photometric monitoring campaign of the 15 galactic open clusters of different ages carried out under the international Uzbek-Indian research project. We obtained the extensive photometric time series database of these clusters during 3 years in 2021-2023. In addition to new data set, the time series were also obtained for 7 clusters earlier in 2003, i.e. with the twenty-year break. The aggregate analysis, together with the available data obtained by *TESS* and *Gaia* missions, made it possible to discover a significant number of new variable stars in different clusters, check the few known variables in these clusters and determine their belonging to the cluster (membership), their kinematics, distance, age and other parameters of the native cluster. The resulting observational database and the current results of its analysis in combination with *TESS* and other data is discussed. Processing and in-depth analysis of this data using original pipelines and existed *BigData* analysis software for *Gaia* and *TESS* is currently ongoing together with our Indian partners.

Astrometry in Africa

Dr Aletha de Witt

South African Radio Astronomy Observatory (SARAO)/ Department of Science and Innovation (DSI)

Abstract

Africa has a rich history of astrometry dating back to ancient times when celestial observations were crucial for navigation and timekeeping. Modern astronomy in South Africa originates from the maritime challenges faced by European explorers along the coastline during the 17th/18th centuries. The need for precise stellar positions for navigation led to the establishment of the Royal Observatory at the Cape of Good Hope in 1820, now the South African Astronomical Observatory (SAAO). Established in 1974, the Hartebeesthoek Radio Astronomy Observatory (HartRAO) remains a vital contributor to the Celestial Reference Frame (CRF) through Very Long Baseline Interferometry (VLBI), housing Africa's only VLBI-capable radio telescope for astrometry. Looking forward, the addition of a new geodetic telescope at HartRAO and potentially others to the VLBI Global Observing System (VGOS) will significantly contribute to the VGOS CRF. The Africa Millimetre Telescope (AMT) project plans a millimetre radio telescope in Namibia, linking to the Event Horizon Telescope (EHT) Network as Africa's first. Additional millimetre telescopes, including on Mount Kilimanjaro, are considered, augmenting astrometric capabilities for CRF work. The African VLBI Network (AVN) project aims to establish VLBI-capable radio telescopes in the African SKA partner countries. Initiatives like Ghana's conversion of a telecommunications antenna into a radio telescope and plans for a new telescope in Botswana exemplify this progress. The SKA itself in VLBI mode will play a crucial role in detecting new, weaker radio sources and measuring their astrometric positions with sub-milliarcsecond precision. All these efforts promise a vibrant future for African astrometry.

Modern astrometry: Gaia, VLBI, and beyond

Prof Dr Sergei Klioner

Lohrmann Observatory, Technische Universität Dresden, 01062 Dresden, Germany

Abstract

The present state-of-the-art in astrometry will be reviewed. After a very brief historical overview, the status of the optical astrometry with Gaia will be discussed. Advantages and disadvantages of a Gaia-type astrometry and the radio astrometry with VLBI will be summarized. The problems related to the use of different wave-bands for astrometry will be discussed as well.

Characterising Gaia's Compact Object-Luminous Companion Binaries using Multi-wavelength Followup

Dr. Sourav Chatterjee, Mr. Anindya Ganguly

Tata Institute of Fundamental Research

Abstract

Gaia's astrometry has revealed over one hundred candidate compact objects (COs) by resolving the orbital motions of the luminous companions (LCs) in wide orbits around them. While astrometric solutions provide constraints on the mass function of these binaries, it is crucial to estimate the stellar properties of the LCs and COs for categorisation. Such characterisation would also help us constrain progenitor properties such as metallicity and age for the COs, a crucial ingredient to improve detailed models of supernova and CO formation. We use multi-wavelength followup studies spanning infrared (IR) to ultraviolet (UV) for the CO-LC binary candidates identified from Gaia's third data release to construct their spectral energy distributions (SEDs). Using SED modelling we constrain the stellar properties for the LCs including age, metallicity, mass, radius, bolometric luminosity, and effective temperature. In several cases, we can clearly identify the CO as white dwarf (WD) from significant excess UV flux relative to the expected SED from the LC. For these, we constrain WD properties including age, effective temperature, mass, and radius. Deep radio followup is underway for several of these candidate CO-LC binaries. To improve the existing census of WD-MS binaries, we have developed a novel method to identify them even when they are hidden within the main-sequence of an optical CMD by their relative locations on multiwavelength CMDs followed by confirmation through SED modeling. I will talk about our latest key results.

Astrometry of Exoplanets Using Optical Interferometry: Insights from the GRAVITY Instrument

Dr. Sylvestre Lacour[1], ExoGRAVITY Collaboration[2]

[1]Observatoire de Paris. [2]..

Abstract

In March 2019, the GRAVITY collaboration unveiled the first spectrum and astrometry of an exoplanet achieved through optical interferometry. Four years on, we reflect on how this technique has changed our view of imaged exoplanets, offering enhanced astrometry (typically by several tens of milliarcseconds) and superior spectra compared to those obtained with single telescopes. But to what extent has this transformation occurred? What levels of precision can we now achieve, and what are the implications? In this talk, I will detail the method that facilitated these high-contrast observations and weigh its pros and cons. Furthermore, I will highlight some of the key results to date and explore the future prospects of this technique.

Astrometric bias caused by inhomogeneous background

Dr. Anatoliy Ivantsov

Royal Observatory of Belgium

Abstract

All kinds of measurements are taken against some background. The greater the signal-to-noise ratio is, the smaller error is expected in both position and magnitude of an object. If we take measurements of the objects that are slightly less than the magnitude of the background, their positions will be affected by background inhomogeneity. In the case of point sources with the Gaussian-like distribution of intensity, the symmetry is broken, and the source's position is biased. We provide an analytic solution for the bias of the Gaussian image if the neighbourhood background gradient is known or measured. The solution explains the exponential-looking degradation of the astrometric errors with respect to the magnitude and gives a way to balance the reduction by the proper weights introduced. The abstraction allows correcting the bias in the astrometry of Gaussian-like sources whatever wavelengths or instruments are used.

[1]Jet Propulsion Laboratory, California Institute of Technology. [2]National Radio Astronomy Observatory. [3]Oxford Quantum Circuits. [4]Yebes Observatory. [5]Ozyegin University. [6]California Institute of Technology

Abstract

NASA's deep space spacecraft are navigated via astrometric measurements relative to the Celestial Reference Frame. There is an increased emphasis on the use of K band (25.5 GHz–27 GHz) and Ka band (31.8 GHz–32.3 GHz) communications, both to increase the downlink data rates and because of spectral congestion and interference at lower frequencies. The same equipment used for communications is used also for generating signals for navigation, with an aspect of deep space navigation involving relative astrometry between the spacecraft and International Celestial Reference Frame (ICRF) sources. The IAU recently adopted the third ICRF, which now includes observations at K- and Ka bands as well as the legacy S-X–reference frame. We describe a prototype wide-band receiver system for the Very Long Baseline Array (VLBA) that covers from 8 GHz to 40 GHz simultaneously. The system consists of a quadridge feed horn, a cryogenic package containing wide-band low-noise amplifiers (LNAs), and a downconverter to transform the received signals to the VLBA's signal transport system. The receiving system was tested at the Jet Propulsion Laboratory, California Institute of Technology, then deployed to the VLBA's Owens Valley antenna. We describe its performance, which includes detection of fringes in observations with other VLBA antennas.

Part of this research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration. The National Radio Astronomy Observatory is a facility of the National Science Foundation operated under cooperative agreement by Associated Universities, Inc.

Study of the hadronic synchrotron mirror model for orphan flares in blazars - Application to3C279

Mrs Laenita De Jonge, Professor Markus Böttcher

North West University (NWU)

Abstract

Blazars are a class of Active Galactic Nuclei (AGN), found in the centres of elliptical galaxies, that are radio loud and have a small angle between the jet and the observer's line of sight. In some cases, flaring events in one frequency band are not accompanied by flaring in other bands. Such events are called orphan flares. The causes of this variability and conditions in and location of the high energy emission region are not completely understood. As a possible explanation for rapid orphan gamma-ray variability, the hadronic synchrotron mirror model has been suggested in previous work. A TeV orphan flare was observed on the 28th of January 2018 by the H.E.S.S. observatory from 3C 279. A primary flare was observed 11 days earlier by Fermi-LAT. The hadronic synchrotron mirror model is applied to this flare. A study uses the SED and multi-wavelength light curve results to determine which parameters provide the best fit and to draw conclusions about the radiation mechanism that caused this orphan flare. A search for neutrino emission is also conducted to establish if orphan flares are a possible source.

[1]National Radio Astronomy Observatory. [2]Fourier Space. [3]Swinburne University of Technology. [4]Digital Radiometer Systems LLC

Abstract

The Very Long Baseline Array (VLBA) is the premier astrometric instrument, used for both defining the International Celestial Reference Frame and for determining positions and motion of sources throughout the Milky Way and the Universe. Part of this success comes from the capabilities provided by the current backend for the VLBA, the Roach Digital Backend (RDBE). The RDBE has been in operation since 2011, and ushered in a new era of higher sensitivity observations, but it has recently become difficult to maintain. The National Radio Astronomy Observatory (NRAO) has been working through more frequent failures and fewer available spare parts. We have undertaken the VLBA New Digital Architecture (VNDA) project to modernize the digital backend system on the VLBA.

VNDA will allow for a larger number of configuration combinations of bandwidth, bits per sample, and number of channels. VNDA will also remove restrictions on tuning within the band, useful for working around parts of the band with strong RFI. Finally, VNDA has the capacity to accommodate future VLBA upgrades, for example new receivers or updates to the IF system. The expanded capabilities VNDA provides will allow the VLBA to continue performing as a premier astrometric instrument as we anticipate the capabilities of the ngVLA.

A Telescope on Mount Kilimanjaro, Tanzania

Dr Noorali Jiwaji, Dr Gordon MacLeod, DR Said Ally

Open University of Tanzania

Abstract

The genesis of a telescope on Mount Kilimanjaro was born in 2010 during a visit to South Africa by a scientific delegation from Tanzania. It was proposed to explore the possibility of astronomy on Mount Kilimanjaro. Desktop studies suggest sites on the Saddle, an area of about 20 square kilometers above 4,500-m, may be suitable for millimeter and submillimeter wavelength astronomy. However, appropriate site testing is required to verify. We have navigated a lengthy process to receive permission to carry out preliminary atmospheric transmission studies on Kilimanjaro, and we anticipate starting this activity at a 4,720m elevation site in the near future.

Following these studies, installation of a 10-m class radio telescope (actual size not yet determined) with high efficiency (~70% at up to 230 GHz) will be explored. Our goals are to operate as a stand-alone observatory for a range of radio science topics, and to participate in high frequency Very Long Baseline Interferometry experiments that resolve the event horizons of nearby supermassive black holes. Other serious issues must still be overcome, in particular environmental and aesthetic impact during the construction phase, in addition to addressing cultural, economic and educational issues and opportunities. These issues will be discussed here.

Update of the CNS5 catalogue: a multi-wavelength census of the solarneighbourhood

Alex Golovin, Dr. Sabine Reffert

Landessternwarte, Zentrum für Astronomie der Universität Heidelberg, Königstuhl 12, 69117 Heidelberg, Germany

Abstract

Catalogues of nearby stars represent the best-characterised stellar and substellar populations and, as such, are fundamental tools for studying the solar neighbourhood and the composition of the Galactic disk, for selecting targets for exoplanet surveys, and for testing stellar evolution models.
By combining astrometry across different wavelengths, the Fifth Catalogue of Nearby Stars (CNS5) provides the most volume-complete sample of all known stars and brown dwarfs which are possibly located within 25 pc of the Sun.
The CNS5 is compiled based on trigonometric parallaxes from Gaia DR3 and Hipparcos, and supplemented with astrometric data from Spitzer and ground-based surveys carried out in the infrared, as well as radio astrometry from ALMA, VLA, and VLBA.
After its initial release, the CNS5 has been continuously updated with observational data for nearby stars from various sources.
In this talk, we review this census, including new additions to the 25 pc sample, and present an update of the CNS5.
We also discuss how our methods for constructing an astrometrically clean catalogue of nearby stars have enabled us to discover and characterise new nearby white dwarfs.

KOSMIC: K-band VLBI Observations with Improved Scheduling and Ionospheric Corrections

Benedikt Soja[1], Aletha de Witt[2], Marcel Iten[1], Arno Rüegg[1], Matthias Schartner[1], Hana Krásná[3], Marisa Nickola[2]

[1]ETH Zurich. [2]South African Radio Astronomy Observatory. [3]Technische Universität Wien

Abstract

Very Long Baseline Interferometry (VLBI) has revolutionized astrometry by accurately measuring the angular directions of compact extra-galactic radio sources, forming the celestial reference frame (CRF). The K-band (24 GHz) CRF, introduced in the multi-wavelength ICRF3, promises enhanced precision over lower frequencies but faces challenges like ionospheric effects and network geometry issues. The project KOSMIC, a consortium between ETH Zurich, HartRAO, and TU Wien, aims to address these challenges to enhance the precision and stability of the K-band CRF, impacting astronomy, geodesy, and space exploration. These efforts align with the IAU's ICRF maintenance call and support multi-wavelength CRF development.

In the first part of the project, we will develop a machine learning-based ionospheric model to optimally correct K-band VLBI observation for ionospheric effects. The model will rely on Global Navigation Satellite System (GNSS) data and be specifically tuned to perform well at the sites of the VLBI stations participating in K-band efforts. In the second part of the project, advanced scheduling techniques based on the VieSched++ software will be implemented in K-band observation plans to partially compensate for the limitations of the network geometry.

This contribution provides an overview of the project, outlining our strategies to address the objectives and highlighting the initial results achieved. Our new approaches regarding ionospheric corrections and scheduling will be operationally implemented to enhance future K-band observations and the corresponding CRF.

Comprehensive Compilation of Stellar Data in M33's Central Region: Unveiling the Final-Stage Evolution Through Near-Infrared Survey

Ms Mina Alizadeh[1,2], Dr. Atefeh Javadi[2], Prof. Jacco Van Loon[3], Dr. Yousef Ali Abedini[1], Dr. Hedieh Abdollahi[2]

[1]Zanjan University. [2]IPM (Institute for theoretical Physics and Mathematics). [3]Keele University

Abstract

We obtained data using three cameras at the UK InfraRed Telescope (UKIRT) between 2003 and 2007. The observations in the K-band were conducted by the UKIRT Fast-Track Imager (UFTI) over three consecutive nights in August 2005. The Wide Field Camera (WFCAM) data in the J and H bands were collected between 2005 and 2007. Additionally, UIST data in the K-band for the central region of M33 were gathered from 2003 to 2007.

Our focus was on stars in the final stage of their evolution, where luminosity is more directly related to birth mass. By combining data from multiple instruments and projects, we aim to identify long-period variables in the galaxy's central region, as this area provides the deepest and most comprehensive investigation of the galactic center due to the nature of the data. The identification of variables will involve photometry on the WFCAM data with PSF calibration followed by a re-examination of the data.

ICRS realizations and their inherent inconsistencies: a geodesist view

Dr. Maria Karbon[1], Santiago Belda[1], Esther Azcue[2], Jose Manuel Ferrandiz[1], Alberto Escapa[3]

[1]Universidad de Alicante. [2]Instituto Geografico Nacional. [3]Universidad de Leon

Abstract

One of the primary goals of Very Long Baseline Interferometry (VLBI) is the determination of the International Celestial Reference Frame (ICRF). The third realization of the CRF, the ICRF3, was adopted by the IAU in August 2018, which replaced the ICRF2 from 2009. The novelty was the supplement of the catalog at standard geodetic and astrometric radio frequencies (8.4 and 2.3 GHz) with data collected at higher radio frequencies (24 GHz and dual-frequency 32 and 8.4 GHz). However, in contrast to the standard procedure in geodesy, e.g. in the determination of the International Terrestial Reference Frame (ITRF) or the Earth rotation parameters (EOP), where intra- and inter-technique combinations are performed operationally, the three individual catalogs forming the ICRF3 stand independently from each another. The CRF realized by Gaia stands alone as well.

Within this work we investigate known inconsistencies and systematics inherent to the ICRF3 (and in relation to Gaia-CRF) and quantify their impact, point out unsolved issues in the determination and realization of these frames and suggest methods to address them. We illustrate the methods and works pursued in geodesy to reach the highest possible precision.

Photometry of a Select Sample of Large Magellanic Cloud Cepheids: Light Curves, Color Curves, Amplitudes, Mean magnitudes and Multi-Wavelength Covariance across the Optical (BVI), Near-Infrared (JHK) and Mid-Infrared (3.5 and 4.5 micron) Bands.

Mr Mahdi Abdollahi[1], Prof. Barry F. Madore[2,3], Dr. Atefeh Javadi[1]

[1]School of Astronomy, Institute for Research in Fundamental Sciences (IPM). [2]The Observatories, Carnegie Institution for Science. [3]Department of Astronomy & Astrophysics, University of Chicago

Abstract

Thanks to the multiwavelength data collected in several surveys conducted by TMMT and Spitzer, we can consider the Period-Luminosity (PL) relation from optical to mid-IR. It is evident that as we move to longer wavelengths, the dispersion of PL data decreases, indicating a reduction in statistical errors due to the diminishing effect of temperature. Working in redder wavelengths (near- and mid-IR) provides us with more reliable results, leading to more accurate determinations of H0.

Observations in this range of wavelengths are challenging and often impossible with ground-based telescopes, necessitating space-based telescopes such as JWST. However, these observations are constrained by time limitations due to the many observations they must conduct. This poses a challenge in requiring time-averaged data in subjects like PL relation. This idea emerged from the question: is it possible to derive time-averaged magnitudes from single-epoch observations?

In this project, we aim to discover a relationship to correct random-phase data, resulting in narrower PL data. This method tackles errors originating from the single-epoch observations by utilizing information from observations in another filter, leading to time-averaged data. The technique relies on correlations between residuals from Period-Luminosity (PL) relations and magnitude-magnitude diagrams across various bandpasses, primarily spanning different ranges of wavelengths.

Finally, we selected the J and B bandpasses to calibrate and test our method, with the J bandpass representing the random-phase data component. The findings illustrate that this correction reduces the scatter around the PL fitted line by approximately √2 in the J bandpass, From 0.24 to 0.17 magnitude.

A digital-spectroscopy-type water vapor radiometer for high accuracy radio astrometry

Prof. Hiroshi Imai[1], Prof. Noriyuki Kawaguchi[2]

[1]Kagoshima University. [2]National Astronomical Observatory of Japan

Abstract

We have tested a digital-spectroscopy-type water vapor radiometer (WVR) installed at the Stewart platform focus in one of the VERA (VLBI Exploration of Radio Astrometry) 20-m dish radio telescopes for directly measuring the excess path delay length (EPL) due to Earth's precipitable water vapor toward astrometry targets (i.e. background reference and astrometrically targeted radio sources). Such measurement is crucial to high accuracy astrometry for sources at low telescope elevations (e.g. sources in the Galactic Center observed from VERA in Japan) because the difference in the EPLs towards the targets at slightly different elevations (by degrees) may innegligibly affect the astrometry at a micro-arc seconds level. Although new calibration techniques for VLBI astrometry have been developed, such as the multi-view technique, the WVR technique should be explored for millimeter VLBI astrometry in which a coherent time for fringe visibility integration is too short for applying such new techniques. The WVR based on a compact analogue-digital high-speed sampler enables us to install it on the upper cabin of the telescope. We will present the present status of the development of the WVR technique, in which the measured EPLs shall be applied to more precise calculation of phase-tracking models used for visibility calibration. The feasibility of the WVR technique will be evaluated by comparison between the EPLs derived from the WVR and GNSS station data and improvement of the astrometric accuracy with applying the technique.

[7]National Space Science Center, Chinese Academy of Sciences, Beijing, China

Abstract

By tapping into the unique lunar-based and lunar orbital environment, we have the opportunity to conduct multi-wavelength observations across an extensive range of wavelengths, from EUV to IR. In 2021, our collaborative research teams from Russia and China proposed the construction of a Lunar-based UV-Optical-IR telescope/array for the International Lunar Research Station (ILRS). Since then, we have been continuously refining our scientific objectives. This presentation will explore the scientific goals, simulations of the capabilities, and considerations for payload requirements. The optimized scientific goals of the lunar-based telescope/array are focused on:

1. To conduct a UV sky survey and detailed observations from the lunar surface, create a dynamically updated and comprehensive UV catalog, investigate galaxy formation and evolution, and develop a timeline of galaxy evolution covering 80% of the universe's history.
2. To capture dynamic cosmic "movies" in the near UV band, investigate high-energy transients in the local universe, and comprehensively study the ultraviolet features of variable sources within the Milky Way.
3. To explore the habitability of exoplanets from a fresh and distinctive viewpoint, we will take into account space weather phenomena and the impact of small bodies within planetary systems; Furthermore, to uncover new terrestrial exoplanets within habitable zones, analyze their characteristics, and envision potential future habitable environments for humanity.
4. To investigate the interaction between Earth's magnetosphere and exosphere with the solar wind from an external perspective using a UV telescope on the Moon's orbiter, and to survey the heliosphere in Lyα.

The X/Ka (8.32 GHz) 2024b Celestial Reference Frame: Systematic Errors

Mr. Christopher Jacobs

Jet Propulsion Laboratory, California Institute of Technology

Abstract

The X/Ka-band (8.4/32 GHz) Celestial Reference Frame became one component of the ICRF-3 in 2018. In the six years since, the X/Ka data set has increased by a factor of two as well as adding the much needed north-south geometry from Japan to Australia. Median formal precision is now better than 100 micro-arseconds. The accuracy of the frame is limited by systematic errors larger than the formal precision. The limited network geometry allows for geometric distortions—most notably quadrupole 2,0 distortions. This paper will compare the use of three data weighting methods to account for the dominant noise from wet tropospheric fluctuations and the resulting impact on systematic frame distortions:
1) white noise weighting,
2) elevation dependent white noise,
3) correlated observation noise based on Kolmogorov spectrum troposphere refractivity fluctuations.

Insights into the Synchrotron Polarization Emission from the Bright Gamma Ray Blazars

Dr. Krishna Kumar Singh[1,2], Prof. Peiter J Meintjes[3], Dr. Kuldeep K Yadav[1,2]

[1]Bhabha Atomic Research Centre, Mumbai, India. [2]Homi Bhabha national Institute, Mumbai, India. [3]University of the Free State, Bloemfontein, South Africa

Abstract

Blazars are an extreme class of astrophysical gamma-ray sources powered by accreting super-massive black holes at the center of an active galaxy. They possess oppositely directed relativistic plasma jets emanating from the central engine and oriented towards the Earth. Measurements of strongly polarized radiation from the blazar-jets provide key evidence for the synchrotron emission at low energies ranging from radio to soft X-rays. The highly variable synchrotron radiation with often quite peculiar polarization behavior in the optical waveband is connected to the high energy gamma-ray emission process, which is an open question in the area of blazar research. In this contribution, we investigate the physical properties of the optical polarization from a sample of bright gamma ray blazars. We use the informations obtained from the phenomenology of the optical polarization to study the processes of relativistic particle distribution in the blazar jets.

Quasiperiodic Oscillation in the Gamma-Ray Light Curves of selected Blazar Sources

Ms. Manisha Dwa[1,2], Dr. Niraj Dhital[1]

[1]Tribhuvan University. [2]Nepal Astronomical Society

Abstract

Blazars are one of the brightest and the most energetic objects in the sky whose powerful emission spans the entire electromagnetic spectrum. Detection of quasiperiodic oscillations in the light curves of blazar sources can have important implications including among others the structure and the nature of various regions of the active galactic nuclei.

In this contribution, results from the quasiperiodic oscillation search in the gamma-ray light curves obtained from the Fermi/LAT of the selected blazar sources will be presented. The methodologies used in the work and the plausible scenarios which can explain the observed quasiperiodic oscillations will be presented as well.

PASIPHAE survey : PSF photometry methods for the WALOP instrument

Mr. Kishan Deka

National Center for Nuclear Research, Warsaw, Poland. National Institute of Science Esucation and Research, Bhubaneswar, India

Abstract

Polarization studies of cosmic microwave background radiation (CMBR) are useful in order to probe the large scale structures and fluctuations in the early universe. But, contamination from various sources in the CMB maps poses a great problem to observational cosmologists. One of the main sources of contamination is the polarized emission from prolate dust particles aligned with the galactic magnetic field. Understanding the magnetic field structure of our galaxy is important to subtract these foreground contaminations. Linear polarisation data of stars provides a unique way to study the intervening galactic field tomography of the Milkyway galaxy. This the main purpose of the PASIPHAE survey which aims at creating a dataset of polarization of numerous stars in the galactic polar regions with the help of upcoming state-of-the-art polarimeter named WALOP. In this presentaion, I will discuss how we use polarization data of stars to create a tomographic map of the galactic magnetic field in the context of the PASIPHAE survey. High-sensitivity polarimetric experiments with such scientific goals demand high accuracy in photometric measurements. The WALOP instruments are designed to have a large field of view (about 30 × 30 arcminutes) that can measure the stokes parameters (I, Q, U) of multiple stars in one shot with 0.1% accuracy. I will present the photometry and polarimetry methods we used in developing the pipeline for carrying out high accuracy polarimetry with the WALOP instrument. In this work, we present a method known as PSF photometry for the WALOP instrument.

Towards the next multi-waveband realization of the International Celestial Reference Frame

Dr. Patrick Charlot

Laboratoire d'Astrophysique de Bordeaux, Université de Bordeaux, CNRS, France

Abstract

This presentation will review the current status of the VLBI frames at 8 GHz (X band), 24 GHz (K band) and 32 GHz (Ka band) in terms of sky coverage, precision and systematic errors, in view of preparing for the next realization of the International Celestial Reference Frame (ICRF) which will be multi-waveband. As such, the next ICRF will incorporate the Gaia optical frame in addition to the three above radio bands. Potential frames that may emerge at other radio frequencies in the coming years, namely at 43 GHz (Q band) or with the VLBI Global Observing System of the International VLBI Service for geodesy and astrometry, will also be covered. Finally, questions relating specifically to the construction of the multi-waveband frame like treatment of Galactocentric acceleration, alignment of the individual frames in the different bands, dealing with non-uniform sky distributions, along with considerations regarding wavelength and time-dependent source positions will be addressed. The targeted date for completion of the next ICRF, as proposed by the IAU Multi-waveband ICRF Working Group, is 2027, meaning a possible adoption by the IAU General Assembly that will take place the same year.

VLBI monitoring of the structure of the ICRF sources - The Bordeaux VLBI Image Database

Arnaud Collioud, Patrick Charlot

Laboratoire d'Astrophysique de Bordeaux, Université de Bordeaux, CNRS, Pessac, France

Abstract

The extragalactic radio sources that make up the International Celestial Reference Frame (ICRF) can exhibit extended and time-variable brightness distributions (or structures) on VLBI scales, setting limits on the accuracy of the astrometric source positions determined from VLBI. For this reason, regular VLBI observations are organized to image and monitor these structures. The primary observations used for this purpose are the so-called ``Research \& Development with the VLBA'' (RDV) sessions, initiated almost three decades ago. Systematic imaging of the sources observed in these sessions is carried out by the Bordeaux group with the goal of tracking the structural evolution of the ICRF sources on the long-term. The VLBI images produced along with metrics that characterize the source structure are made available to the scientific community via the Bordeaux VLBI Image Database (BVID). Occasionally, other sessions, either at higher radio frequencies, i.e. K band (24 GHz) and Q band (43 GHz), or from other observing programs, are also used for imaging, At present, the database includes more than 8000 VLBI images for more than 1500 sources, with up to 50+ epochs per source. The available data may be used for astrometric and astrophysical research, like selecting the defining sources for the ICRF, modeling source structure in astrometric and geodetic VLBI, and studying the nature and evolution of the sources. The BVID is accessible at the following url: https://bvid.astrophy.u-bordeaux.fr

Dynamical Masses of Young Stellar Multiple Systems with the VLBA (DYNAMO-VLBA)

Dr. Sergio Dzib Quijano

Max-Planck-Institut fuer Radioastronomy

Abstract

Very Long Baseline Interferometry (VLBI) provides ultra high angular resolution images and has been used for stellar astrometry for decades. As part of our previous Very Long Baseline Array (VLBA) observations, we unveiled a significant number of tight binary and multiple pre-main-sequence stars, whose components have detectable radio emission and typical separations of the order of milli-arcseconds; thus Gaia will not provide information on their orbital parameters and VLBA observations are an excellent tool to keep studying them. Dynamical mass estimations are free of assumptions on the physical parameters of the stars and, thus, DYNAMO-VLBA results could be used to test evolutionary models of pre-main-sequence stars. I will present the first Dynamical mass determinations of young binary systems with DYNAMO-VLBA. Our first findings show that the dynamical masses of these systems do not correspond with those expected from evolutionary models.

The Magellanic Clouds with high resolution glasses

Óscar Jiménez-Arranz

Institut de Ciències del Cosmos (ICCUB)

Abstract

The exquisite astrometric dataset that Gaia DR3 offers to the scientific community makes the Magellanic Clouds (XMC) a unique test laboratory to investigate and refine methodologies and models. Classification strategies based on Neural Networks allow to select LMC and SMC samples with less than 10% contamination from the MW (Jiménez-Arranz+23a,b). Also, the LMC is the first galaxy for which we can map a 3D velocity field of the complete galaxy (Jiménez-Arranz+23a) and endeavour dynamical studies in detail, such as the determination of the LMC bar pattern speed using different methods (Jiménez-Arranz+23c). For the first time, we can analyse the internal kinematics of an external galaxy and compare them with what theoretical models predict. The results highlight the evidence of the need of high resolution simulations to provide a dynamical interpretation of the information shown by the data. In this talk, we introduce KRATOS (Jimenez-Arranz+24, submitted), a suite of 28 pure N-body simulations of isolated and interacting LMC-like galaxies, to study the formation of substructures in their disc after the interaction with an SMC-mass galaxy, and a review of the planned scientific exploitation of these data. We also discuss the potential impact of the upcoming astrometric mission GaiaNIR on our understanding of these galaxies.

Use of GPS satellites for time calibration

Dr. David Tholen

University of Hawaii

Abstract

The accurate determination of orbits for solar system objects depends not only on having accurate positional information for the target, but also accurate temporal information. The Gaia reference catalogs have enabled a significant improvement in the accuracy of positional information, but they have done nothing for the improvement of temporal information. Even if computer clocks are synchronized using NTP software or other similar technology, the latencies in mechanical shutters can introduce small delays in the occurrence of an observation relative to the timestamp provided. We have been observing GPS satellites during evening and morning twilight to confirm the accuracy of the temporal information. By comparing the measured position of the satellite with the well-known ephemeris position, it is possible to measure shutter delays down to the few millisecond level. The details of our procedures will be presented during the meeting.

VLBI detections of nearby (<100 pc) young stars

Dr. Sergio Dzib

Max-Planck-Institut fuer Radioastronomy

Abstract

I will present a new project aiming to increase the number of sources with Very Long Baseline Interferometry (VLBI) astrometry available for comparison with the Gaia results. Using the Very Long Baseline Array, we have observed 31 stars with recently reported radio emission, located <100 pc from the Sun, and all are in the Gaia DR3 catalog. Our first observations yielded 10 detections (a 30% detection rate). Using the astrometric Gaia results, we have extrapolated the target positions to the epochs of our radio observations and compared them with the position of the radio sources. I will discuss the results of this analysis and the importance for further Gaia - VLBI stellar astrometry comparisons.

Unveiling the Multi-wavelength connection from Correlations of astronomical and astrometric/geodetic data of AGN sources in the K-band Celestial Reference Frame (CRF) Catalogue.

Dr. Pfesesani van Zyl[1], Dr. Aletha de Witt,[2], Dr. Janeth Valverde,[3], Dr. Jeffrey Hodgson,[4], Dr. Hana Krasna,[5]

[1]South African Radio Astronomy Observatory, South Africa. [2]South African Radio Astronomy Observatory (SARAO), South Africa. [3]NASA-GSFC/UMBC, United States. [4]Sejong University (SU), South Korea. [5]Technische Universit ät Wien (TU Wien), Austria

Abstract

Active galactic nuclei (AGN) constitute the largest population in the gamma-ray sky, and host the most extreme environments capable of accelerating particles that radiate in the entire electromagnetic spectrum, while also launching stable mega-parsec (Mpc) scale jets. However, understanding the nature and location of their fast variability emission zone remains a challenge, necessitating population studies to better grasp the characteristics of these intricate objects.

The K-band Celestial Reference Frame (CRF) catalogue project recently published 5078 high-resolution Very Long Baseline Interferometry (VLBI) images, capturing 731 AGNs across 27 epochs. Leveraging this unique and incredibly extensive dataset, our study integrated VLBI flux-density time-series and images, complemented by gamma-ray data from the space-based Fermi Large Area Telescope (Fermi-LAT, 0.1->300 GeV).

We focused on investigating the multi-wavelength connections within 43 AGNs carefully selected from the K-band CRF catalogue. Our analysis delved into the intricate relationships among radio and gamma-ray, and positional time-series data from astronomical and astrometric/geodetic observations. Preliminary results suggest the existence of correlations between the positional offsets and gamma-ray data, as well as between radio and gamma-ray data in select AGNs. Additionally, intriguing patterns of long-term variability among the chosen AGNs were also uncovered, shedding light on the dynamic interplay between radio and gamma-ray emissions.

These findings offer crucial insights into the underlying physical processes, contributing to a deeper understanding of the astrophysical mechanisms governing AGN behavior. Our work represents an important step forward in our ongoing pursuit to comprehend the complex nature of AGN.

The GaiaNIR mission: Future Space Astrometry in the Near Infrared

David Hobbs

Lund University

Abstract

Our Galaxy contains many different types of stars and planets, interstellar gas and dust, and dark matter. These components are widely distributed in age, reflecting their formation history, and in space, reflecting their birth place and subsequent motion. Objects in the Galaxy move in a variety of orbits that are determined by the gravitational force, and have complex distributions of different stellar types, reflecting star formation and gas-accretion history. Understanding all these aspects in one coherent picture is being partially achieved by Gaia, which surveys around 1% of the Galaxy and is still ongoing today. However much more could be done by using Near InfraRed (NIR) light to peer through the dust and gas to reveal the hidden regions of the Galaxy.

A new all-sky NIR astrometric mission will expand and improve on the science of Gaia using basic astrometry. NIR astrometry is crucial for penetrating obscured regions and for observing intrinsically red objects. The new mission is aimed at surveying around 12 billion stars in the Galaxy, revealing important new regions obscured by interstellar gas and dust while also improving on the accuracy of the previous results from Gaia. The mission will explore the Galaxy, particularly the very important hidden regions, to reveal nature's true complexity and beauty in action.

In 2019 ESA announced the next planning cycle for their long term Science Programme, called Voyage 2050. The program called for White Papers outlining new ideas for future space mission themes. In June 2021 Voyage 2050 finally set sail, with ESA having chosen its future science mission themes. Our proposal on All-Sky Visible and Near Infrared Space Astrometry has been selected as one of two possible themes for a future Large category mission for ESA or as a Medium class mission with international partners. This talk will give an update on the science goals, the mission design and its current status.

Astrometry with the Africa Millimetre Telescope

Michael Janssen

Department of Astrophysics, Institute for Mathematics, Astrophysics and Particle Physics (IMAPP), Radboud University, P.O. Box 9010, 6500 GL Nijmegen, The Netherlands. Max-Planck-Institut für Radioastronomie, Auf dem Hügel 69, D-53121 Bonn, Germany

Abstract

I will describe the Africa Millimetre Telescope (AMT), which is planned to be built on top of the Gamsberg in Namibia and be operational in 2028. As the first millimetre telescope in Africa, the primary focus is to enhance observations of the Event Horizon Telescope. The AMT will facilitate dynamic image reconstructions of Sgr A* and improve our current GR, plasma, accretion, and jet physics tests. Centimetre wavelength receivers for the AMT are planned to be added in the future. This will enable participation in VLBI astrometric observations with the EVN and AVN. I will also describe more exploratory astrometric applications at the shorter millimetre wavelengths. Here, black hole shadows can serve as reliable reference points, unaffected by core-shift effects that have to be taken into account for astrometry with active galactic nuclei at lower observing frequencies. Finally, mm VLBI in-beam phase referencing will be able to improve the astrometry of our galactic centre, particularly the alignment of galactic radio and infrared reference frames. Here, the advantage is that the short wavelength observations are less affected by the interstellar scattering screen towards Sgr A*.

Advancements and Innovations in the Korean VLBI Network (KVN) for mm-VLBI Astrometry and Geodesy

Taehyun Jung

Korea Astronomy and Space Science Institute (KASI)

Abstract

The Korean VLBI Network (KVN) is distinguished by its unique multi-frequency receiving system, allowing simultaneous observations across four bands (18-26, 35-50, 85-116, 124-142 GHz). This capability greatly enhances our broadband observational capabilities in radio astronomy and geodesy. Overcoming atmospheric phase fluctuations, a major challenge in millimeter VLBI (mm-VLBI), is made possible through KVN's innovative calibration technique known as Frequency Phase Transfer (FPT). Consequently, multi-frequency astrometry at mm-VLBI, extending up to 130 GHz, has become feasible, together with the detection of the largest number of sources at this frequency by KVN. These broadband multi-frequency radio observations open up new avenues for VLBI astrometric and geodetic studies.

In this presentation, I will introduce our recent advancements and innovations, including: (1) the first geodetic observation results at 22/43/86/129GHz, (2) the development of a photonic instrumental phase calibration system, and (3) the establishment of common time/frequency standards across the KVN through a fiber network. I will also discuss the synergies and future prospects from these developments for astrometry and geodesy.

Mapping the Distribution of Gamma-Ray Bursts using Open Data GIS

Mr Mercy Akintola

AfAS

Abstract

1. Gamma-ray bursts (GRBs) are fascinating astronomical phenomena thought to be caused by the collapse of massive stars or the merger of binary neutron stars. To gain insights into the distribution and properties of GRBs, we used open data GIS to map the distribution of GRBs in the sky. We collected data on GRBs from publicly available databases such as the Gamma-ray Burst Coordinate Network (GCN), the Gamma-Ray Burst Monitor (GBM), and the Swift Burst Alert Telescope (BAT), and conducted spatial analysis to identify regions of the universe with high and low densities of GRBs. Our analysis revealed that GRBs are distributed non-uniformly in the sky, with a higher density of GRBs observed in certain regions of the universe. I identified several clusters of GRBs that were located near each other in space, suggesting that they may have a common origin. Our density maps showed that GRBs are most common in the outskirts of galaxies, where star formation is also high. These results suggest that the formation of GRBs is closely linked to the formation and evolution of stars in galaxies. My findings demonstrate the power of open data GIS in providing new insights into the distribution and properties of astronomical phenomena, and highlight the importance of open data sharing in advancing scientific research.

Keywords: open data GIS, gamma-ray bursts, spatial analysis, clustering analysis, kernel density analysis.

Wide-field gamma-ray observatories as probes of fundamental physics

Professor Vitor de Souza

University of São Paulo

Abstract

Wide-field of view gamma-ray observatories detect the photons with highest energy known in the Universe and therefore their data offers an unprecedented test for fundamental physics and beyond the standard model proposals. Interactions of the very energetic photons with the intergalactic media or the presence of anomalous effects allows the test for Lorentz Invariance Violation, axion-like particles and dark matter candidates. The removal of systematic effects and false-positive signals requests the detection of a large population of sources from a variety of types at a wide range of distances and directions highlighting the potential of wide-field of view gamma-ray observatories in relation to other techniques. In this talk, we will review the current limits on Lorentz Invariance Violation, axion-like particles and dark matter calculated with the use of high-energy gamma-rays. We will also discuss the possible enhancements in detection and data analysis achievable with the next generation of observatories.

Probing Gamma-Ray Bursts as Cosmological Standard Candles using Spectral information in Machine Learning models

Ms Tamador Aldowma[1,2], Prof Soebur Razzaque[1]

[1]University of Johannesburg. [2]Omdurman Islamic University

Abstract

Gamma-ray bursts (GRBs) represent the most powerful explosions detected across electromagnetic wavebands, originating from the deaths of massive stars (Long-duration) or the merger of two neutron stars (Short-duration). GRBs have been observed from redshift up to z = 9.2, underlining their significance as cosmic probes similar to supernovae type Ia. Extensive efforts have been devoted to using GRBs as cosmological standard candles, leading to the discovery of several empirical relations. In this study, we leverage GRB data from the Fermi-GBM and Kouns-Wind catalogs to estimate pseudo-redshifts for a number of GRBs. This estimation is accomplished by applying Machine Learning techniques, specifically deep neural networks in stacking with the Random Forest algorithm, forming an ensemble model. Subsequently, we conduct a joint spectral analysis using data from Fermi (GBM-LAT) and Swift (BAT-XRT) to attain the most optimal fit, using the ThreeML software. Using the best-fit spectral parameters alongside the pseudo-redshift data, we investigate the Amati relation, a correlation between the intrinsic peak energy ($E_{i,peak}$) of the spectrum, and isotropic energy (E_{iso}) over the burst duration (T_{90}). Furthermore, we also explore the Yonetuko relation, which correlates between Ei, peak, and the peak isotropic luminosity (L_{iso}). These analyses aim to deepen our understanding of GRB characteristics and their potential as cosmological standard candles.

Investigate the impact of magnetar on the kilonova afterglow emission in short GRBs through late-time radio observations.

Dr. Ankur Ghosh[1], Professor Soebur Razzaque[1], Dr. Kuntal Misra[2], Dr. Resmi Lekshmi[3], Mr. C.S Vaishnava[4], Professor K.G. Arun[5], Dr. Amitesh Omar[6]

[1]CAPP, University of Johannesburg, South Africa. [2]Aryabhatta Research Institute of observational sciencES (ARIES), India. [3]Indian Institute of Space Science and Technology (IIST), India. [4]Physical Research Laboratory (PRL), India. [5]Chennai Mathematical Institute (CMI), India. [6]Indian Institute of Technology (IIT) Kanpur, India

Abstract

The coincident detection of gravitational waves (GW 170817) and short gamma-ray bursts (GRB 170817A) confirmed their common origin from the coalescence of binary neutron stars (BNS). Depending on the BNS masses and equation of states, the outcome could be a black hole or a millisecond magnetar. In the presence of a magnetar, a significant portion of its rotational energy is transferred to the emerging ejecta, leading to late-time radio brightening known as "kilonova afterglow" emission upon interaction with the ambient medium. Detection of this late-time radio brightening in short GRBs has profound implications for understanding the progenitor physics. This study presents the deepest and most extensive search for late-time radio emission from short GRBs until 2016, incorporating proper frequency regime, wider observation span and relativistic correction. Utilizing the Giant Metrewave Radio Telescope (GMRT) at 1250, 610, and 325 MHz bands, observations were conducted between 2 and 11 years post-burst for five short GRBs. The estimated upper limits are used to constrain the parameters of the burst and its surrounding environment. With appropriate modifications, the magnetar model constrains the number density of the ambient medium for these bursts to be between 10^{-4} and 10^{-2} cm^{-3}. Our analysis rules out a stable magnetar with an energy of 10^{53} erg for four out of the five GRBs in our sample. The upcoming radio telescope like the Square Kilometer Array (SKA) (in MHz frequencies) with increased sensitivity of μJy level will push the detection limits of kilonova afterglow emission at late times.

Multi-messenger synergies with wide-field ground-based gamma-ray observatories

Prof Soebur Razzaque

University of Johannesburg

Abstract

Gamma-ray astronomy is a thriving field with exciting results in the Very-High Energy (VHE, > 100 GeV) range from the Imaging Air-Cherenkov Telescopes (IACTs) and from the wide-field particle detector arrays. The latter have extended the observational range of gamma-ray astronomy beyond 100 TeV. VHE emission from astrophysical sources requires extreme environments where particles accelerate and interact to produce gamma rays, and in case of hadronic interactions, neutrinos. In this talk I will review multi-messenger aspects of astrophysical sources and synergies with ground-based gamma-ray observatories.

Exploring the Influence of Cosmic Voids on the propagation of TeV Gamma Rays and the Puzzle of GRB 221009A

Hassan Abdalla

IPARCOS and Department of EMFTEL, Universidad Complutense de Madrid, E-28040 Madrid, Spain. Department of Astronomy and Meteorology, Omdurman Islamic University, Omdurman 382, Sudan. Centre for Space Research, North-West University, Potchefstroom 2520, South Africa

Abstract

The recent detection of a gamma-ray burst GRB 221009A has drawn attention due to its record brightness and the first-ever detection of very-high energy (VHE, > 10 TeV) gamma rays from a GRB at such redshift z=0.151. This distance is significant enough for severe attenuation of the gamma-ray flux at these energies due to gamma-gamma pair production with the extragalactic background light (EBL). In this talk, I will discuss whether the presence of cosmic voids along our line-of-sight to the source can significantly impact the detectability of such VHE gamma-ray photons andthe prospects for future detection of TeV photons from extragalactic sources, such as GRBs or blazars, could be enhanced if such detections occur in directions where cosmic voids are present.

The Spatial Distribution of GRBs and the Cosmological Principle

Zsolt Bagoly[1,2], Istvan Horvath[1]

[1]University of Public Services. [2]Dept. of Physics of Complex Systems, Eötvös University

Abstract

We made a survey of the spatial distribution of 542 Gamma-Ray Bursts with precisely determined positions. In the northern galactic hemisphere, we observed a notable cluster of four GRBs within a narrow redshift range ($0.59 < z < 0.62$), coinciding with the previously recognized Hercules–Corona Borealis Great Wall (in a redshift range of $0.9 < z < 2.1$). Conversely, in the southern galactic hemisphere, we observed the previously identified Giant GRB Ring within the redshift range of $0.55 < z < 1.35$. Both the Hercules–Corona Borealis Great Wall and the Giant GRB Ring have become more prominent with the expansion of the GRB sample size.

Do optically bright and dark GRBs differ physically?

Lajos G. Balazs[1,2], Zsolt Bagoly[3,4], Istvan I. Racz[3], Istvan Horvath[3]

[1]Dept. of Astronomy, Eötvös University. [2]HUN-REN CSFK Konkoly Observatory. [3]University of Public Services. [4]Dept. of Physics of Complex Systems, Eötvös University

Abstract

Using the discriminant analysis of the multivariate statistical analysis we compared the distribution of the physical quantities of the optically dark and bright GRBs, detected by the BAT and XRT on board of the Swift Satellite. We found that the GRBs having detected optical transients (OT) have systematically higher peak fluxes and lower HI column densities than those without OT.

A decade surveying the extreme cosmos with the HAWC gamma-ray observatory

Dr Alberto Carramiñana

Instituto Nacional de Astrofísica, Óptica y Electrónica (INAOE). The HAWC Collaboration

Abstract

HAWC, the High Altitude Water Cherenkov gamma-ray observatory, is an extended air shower array optimized to survey and monitor celestial sources of TeV gamma rays over two thirds of the sky. Located at 4100m of altitude in the Northern slope of Volcán Sierra Negra, Central México, HAWC has been in full-operations for over nine years. Taking over MILAGRO, its direct predecessor, HAWC has detected over seventy sources of very high-energy gamma rays, the majority of them related to pulsars, the engines behind the previously unknown TeV halos, together with energetic supernova remnants, star forming regions and microquasars, some of these sources emitting well above 100 TeV. Beyond the Milky Way, HAWC has found evidence of TeV emission from about half a dozen of relatively nearby powerful active galactic nuclei. Operated by a multi-national collaboration, HAWC is one of the most relevant scientific projects undertaken by Mexico.

SABHASAT : A GAMMA-RAY BURST DETECTION CUBESAT

Mr Snehadeep Kumar

Kalinga Institute of Industrial Technology

Abstract

SABHASAT, developed by The Nebula Space Organisation, is a pioneering 3U CubeSat engineered for gamma-ray burst observations in Low Earth Orbit (LEO) at 650 km altitude. As the potential first Cubesat gamma-ray observatory in Asia and the world's second, it integrates cutting-edge detector technologies, encompassing an Active Attitude Control System, Distributed Command and Data Handling, Communication systems, Electronic Power System, and Peak Power Tracker.

The mission of SABHASAT centers on realizing innovative, distributed, and modular instruments, emphasizing cost-effectiveness and swift development. Leveraging off-the-shelf technologies in nanosatellites, like CubeSats, showcases their efficient utilization in the space economy, offering solid performance at a constrained cost. Despite a single sensor's compromised effective area compared to conventional gamma-ray detectors, the distributed design allows for an innovative instrument with unexplored perceptivity.

In a proposed cargo configuration within a 1U CubeSat, a scintillator-grounded sensor utilizing Silicon Drift Detectors detects low-energy X-rays and low-energy gamma rays. With a total power consumption of 4W and a weight under 1.5 kg, the cargo unit must meticulously consider resource limitations on a CubeSat. The gamma-ray detection process involves the scintillating target, flash of light collection by the photosensor, and subsequent signal processing via front-end electronics, ADC, and On-Board Computer before transmission to the ground. The gamma-ray detector's core comprises four optically independent scintillating crystals housed in an aluminum casing.

In conclusion, SABHASAT's advanced design and technology contribute significantly to the exploration of space radiation phenomena within the confined parameters of CubeSats, promising valuable insights into solar and gamma-ray bursts.

Gamma-ray Bursts at VHEs

Dmitry Khangulyan

The University of Tokyo. IHEP

Abstract

Recently, the observational study of gamma-ray bursts (GRBs) in the very-high-energy (VHE) regime has advanced with several long-awaited detection with MAGIC, H.E.S.S., and LHAASO telescope systems. Currently, the list of GRBs with VHE emission measured with very high significance, $\sigma \gg 5$, contains GRB 190114C, GRB 190829A, and GRB 221009A. Several more bursts were detected with lower significance or reported as source candidates. Detection of GRB afterglows in the VHE regime allows obtaining essential information on particle acceleration by relativistic shock waves. This makes GRB afterglows to be important sources for high-energy astrophysics and their studies have an exceptionally broad scope. Two detected GRBs provided us with exceptionally viable data because of the proximity (GRB 190829A) and record-breaking luminosity (GRB 221009A). In this case, Cherenkov detectors provide us with detailed spectral information and well-measured light curves. In the former case, one H.E.S.S. revealed an unexpectedly long signal duration, up to 56 hours after the trigger, and accurately measured the spectrum in a relatively broad energy interval, spanning between 0.18 and 3.3TeV. From the latter GRB, LHAASO detected more than 60,000 photons during the onset of the afterglow, which resulted in unprecedentedly accurate measurement of the light curve and VHE spectrum, which extends beyond 10TeV. The obtained temporal and spectral properties of the VHE emission challenged the earlier prediction and promoted further development of existing models and formulation of new approaches. In this talk and will review the key observational findings and developments in the modeling.

Modelling multiwavelength afterglows of the VHE-GRB population

Dr Monica Barnard[1], Dr Ankur Ghosh[1], Dr Jagdish C. Joshi[2], Prof Soebur Razzaque[1]

[1]University of Johannesburg. [2]Aryabhatta research institute of observational sciencES (ARIES), India

Abstract

The recent detections of very-high energy (VHE, ≥ 100 GeV) afterglow emission from several gamma-ray bursts (GRBs) have opened a new window into the GRB science. Until now synchrotron-self-Compton (SSC), assuming both the stellar wind and constant density circumburst scenarios, has been primarily used to model VHE emission from GRBs. Hadronic emission mechanisms such as photo-pion and photo-pair processes, and proton synchrotron have also been considered. We interpret the VHE emission as a combination of external Compton radiation and SSC, in both the stellar wind and constant density environments. We use publicly available NAIMA radiation modelling code to do a population study of VHE afterglow emission from several GRBs via multi-wavelength light curves and energy spectra. NAIMA already includes optimisation tools to fit radiative models to multiwavelength data. Finding a more robust fit of the model to the latest multiwavelength observations implies better constraints on the GRB environment and the particle energy requirements for the emission observed at late times. These findings have implications on future VHE observations of GRBs.

MHD numerical simulations of CWBs in Star forming regions: high energy particles and TeV gamma-rays emission

Prof Diego Falceta-Goncalves

University of Sao Paulo

Abstract

The collision of the stellar winds in massive WR/O binaries produces strong shock fronts, where particles are accelerated to very high energies. Magnetic field is also amplified in the shocked region on which the acceleration of particles greatly depends. In this work, we show high resolution three-dimensional magnetohydrodynamic simulations of colliding winds coupled to the kinematics of passive charged test particles. We show that colliding-wind binaries are indeed able to produce a significant population of high-energy particles beyond TeV energies, in relatively short timescales, compared to the dynamical and diffusion timescales. We provide estimates of detection from ground based telescopes, such as the CTA array.

Mr Esteban Cárdenas[1], Mr Nicolas Noriega[1], Ms Jennifer Chacon-Chavez[2], Dr Nicolás Vásquez[1], Dr Jonathan Quirola-Vásquez[3]

[1]Escuela Politecnica Nacional. [2]Pontificia Universidad Católica de Chile. [3]Radbound University

Abstract

Traditionally, long gamma-ray bursts (LGRBs) have been associated with the collapse of massive stars. However, our systematic search using a recalibrated Epeak-Eiso plane has revealed five LGRBs that defy conventional categorization.Recently, there have been reports of apparent LGRBS, but upon analysis, it has been revealed that they are associated with mergers and exhibit extended emission, leading to confusion during their classification. Through meticulous temporal and spectral analysis, we have delved deeper into the characteristics of these events, providing insights into their elusive progenitors. Our investigation includes a thorough examination of temporal estimators, including emission time, spectral delay, and isotropic energy, derived from Swift GRB observations. Subsequent phases of our research will explore the properties of the host galaxies and the surrounding media to provide a complete understanding of these puzzling phenomena. By challenging established paradigms, our study contributes significantly to the ongoing evolution of GRB classification and improves our understanding of the most powerful explosions in the Universe.

Abstract

Single-Mirror Small-Sized Telescope (SST-1M) was originally developed as a prototype of a Cherenkov telescope by a consortium of institutes from Poland, Switzerland, and the Czech Republic. In 2021 and 2022, two of our SST-1M telescopes were relocated from Poland and re-installed in the Czech Republic.

The prototypes are undergoing commissioning at the Ondřejov observatory, and they have already accumulated dozens of hours of observations. They have successfully observed Cherenkov events in both stereo and mono modes of celestial gamma-ray sources (e.g., Crab Nebula, Mrk 421), demonstrating the suitability of the telescopes for carrying out observations in better astronomical conditions until their final location is decided.

SST-1M, with a 9.42 m^2 multi-segment mirror and a 5.6 m focal length, is optimized to detect high-energy gamma rays, ranging from about 1 TeV up to 300 TeV. The telescopes are equipped with digital DigiCam cameras based on 1296 hexagonal silicon photomultiplier (SiPM) sensors, covering a field of view of 9.1 degrees. The camera has a fully digital trigger system and readout, which can digitize waveforms in individual pixels with 4 ns sampling.

In this contribution, I will provide an overview of the telescope and camera design. Preliminary results obtained from the commissioning data and daily analyses collected at the observatory will be presented.

Latest results from the searches for ultra-high-energy photons

PhD Indira Dajhana Vergara Quispe[1,2], Pierre Auger Collaboration[3]

[1]Institute of Physics La Plata (IFLP), CONICET. [2]National University of La Plata (UNLP). [3]Pierre Auger Observatory

Abstract

The Pierre Auger Observatory is the largest and most accurate air-shower experiment for cosmic rays at ultra-high energy (UHE). An essential characteristic of the Pierre Auger Observatory is the hybrid concept, combining a Surface Detector array (SD) with a Fluorescence Detector (FD), offering a large exposure and unique discrimination capabilities to photons with energy above 10^{17} eV. Currently, the Pierre Auger Observatory, upgraded with multi-hybrid detectors, extends its measurement capabilities to energies as low as approximately 6×10^{16} eV. The results, presented here, are the product of the analysis of signals obtained from both the long-standing and the newly integrated detector components, such as the Underground Muon Detector (UMD) for the AMIGA project. Thus, the analysis of data taken over 20 years, in hybrid mode as well as with the SD alone, allows various searches for UHE photons including the search for a diffuse UHE photon flux, a flux from point sources of UHE photons, and UHE photons from sources of Gravitational Wave events, obtaining the most stringent upper limits on the photon flux in the UHE regime.

Search for GeV Gamma-Ray Emission from SPT-SZ selected Galaxy Clusterswith 15 years of Fermi-LAT data

Mr. Siddhant Manna, Professor Shantanu Desai

Indian Institute of Technology Hyderabad

Abstract

Galaxy clusters could produce gamma-rays from inverse Compton scattering of cosmic ray electrons or hadronic interactions of cosmic ray protons with the intracluster medium. It is still an open question on whether gamma-ray emission (> GeV energies) has been detected from galaxy clusters. We carry out a systematic search for gamma-ray emission based on 300 galaxy clusters selected from the 2500 deg^2 SPT-SZ survey after sorting them in descending order of M_{500}/z^2, using about 15 years of Fermi-LAT data in the energy range between 1-300 GeV. We were able to detect gamma-ray emission with a significance of about 6.1σ from one cluster, viz SPT-CL J2012-5649. The estimated photon energy flux from this cluster is approximately equal to 1.3×10^{-6} MeV cm^{-2} s^{-1}. The gamma-ray signal is observed between 1 − 10 GeV with the best-fit spectral index equal to −3.61 ± 0.33. However, since there are six radio galaxies spatially coincident with SPT-CL J2012-5649 within the Fermi-LAT PSF, we cannot rule out the possibility this signal could be caused by some of these radio galaxies. Six other SPT-SZ clusters show evidence for gamma-ray emission with
significance between 3 − 5σ. None of the remaining clusters show statistically significant evidence for gamma-ray emission.

A RPC-based GRB Hunter

Dr. Piccolo Davide[1], Dr. Barbara Liberti[2], Dr. Giuseppe Di Sciascio[2], Dr Fabio Muleri[3], Dr. Giovanni Piano[3]

[1]INFN - Laboratori Nazionali di Frascati. [2]INFN - Roma Tor Vergata. [3]INAF - IAPS Roma

Abstract

The observation of transient emission of high energy photons (>GeV) starting from the prompt phase is crucial in a multi-messenger study of the Universe.

The Resistive Plate Chambers (RPCs) can be extensively used in Cosmic Ray Physics and Gamma-Ray Astronomy. Indeed, the ARGO-YBJ detector, a 7000 m2 full coverage RPC carpet, was operated at YangBaJing (Tibet, 4300 m asl) with very low maintenance and excellent performance for more than a decade. It provided: high efficiency detection of low energy showers, down to the GeV range, by means of the high granularity of the read-out sampling; wide energy range investigated, up to 10 PeV, by means of the combined digital/charge read-outs; good energy and angular resolutions with unprecedented details in the shower core region.

Therefore, RPCs provide the ideal detector to observe flaring emissions of photons starting from the GeV range from astrophysical objects such as Gamma-Ray Bursts (GRBs) or Active Galactic Nuclei (AGN).

In this contribution a proposal for a RPC-based GRB hunter made by a wide field of view shower array instrumented with a full coverage core made by RPCs is introduced. The activities to build a small size RPC carpet demonstrator to be installed in the framework of a SWGO R&D project and to study the performance of a hybrid system done of WCD tanks and RPC detectors, will also be reported.

Particle Acceleration to Very High Energies in Pulsar Wind Nebulae

Gwenael Giacinti[1], Benoît Cerutti[2], John Kirk[3], Brian Reville[3]

[1]TDLI Shanghai. [2]IPAG Grenoble. [3]MPIK Heidelberg

Abstract

Pulsar wind nebulae (PWNe) accelerate electrons to very high energies (VHE), but the acceleration mechanism(s) and site(s) remain uncertain. We review and discuss here several possible mechanisms. In particular, we discuss particle acceleration at the pulsar wind termination shock (TS). We find that drift motion along the shock surface keeps either electrons or positrons in a ring-shaped region of the TS, close to the equatorial plane of the pulsar, where they are accelerated to VHE by the first-order Fermi mechanism. Applying our findings to the Crab Nebula, we find that both its high-energy synchrotron emission and gamma-ray emission can be reproduced by this model. We show that the recent observations by LHAASO of the Crab Nebula up to PeV energies allow for putting new constraints on parameters of the Crab pulsar wind that are still poorly known. Finally, we present results from Particle-In-Cell simulations of pulsar wind TS. They confirm the above results, and also suggest that a second electron acceleration mechanism (namely, reconnection) operates downstream of the TS, in the equatorial current sheet. We show that the latter provides a natural explanation for the inner-ring knots in the Crab Nebula, whose origin has remained elusive so far. We will also discuss possible origins for the Crab flares detected by Fermi.

Imprint of intrinsic broad-line region absorption in the gamma-ray spectrum of blazar jet

Ms. Sushmita Agarwal[1], Dr. Amit Shukla[1], Prof. Karl Mannheim[2], Dr. Bhargav Vaidya[1], Dr. Biswajit Banerjee[3,4]

[1]Indian Institute of Technology Indore, Indore, India. [2]Julius-Maximilians-Universität Würzburg, Würzburg, Germany. [3]Gran Sasso Science Institute, L'Aquila (AQ), Italy. [4]INFN - Laboratori Nazionali del Gran Sasso, L'Aquila (AQ), Italy

Abstract

When relativistic jets in blazars are directed toward observers, they intensify emitted radiation, condensing the entire output into a focused, point-like object. Blazars typically exhibit emissions spanning the electromagnetic spectrum, spanning from radio frequencies to very high energies. The GeV spectrum within these relativistic jets of blazars is primarily shaped by the non thermal emission processes internal to the jet. However, the external thermal environment surrounding the high-energy emission site is expected to leave an imprint of pair production absorption at high energies, particularly if the emission region resides within the influence of the nearby external jet environment. This could help further constrain the debatable gamma ray dissipation site in blazars.

Our study reveals for the first time, GeV breaks in the range of 40 - 85 GeV, well described by γ-ray absorption through photon-photon pair production on H-alpha or H-beta lines photons , specifically during the high state of the source. Remarkably, this absorption feature is absent during the low flux state, suggesting an additional absorption effect imprinted specifically during the high activity period of the source beyond the expected extragalactic background light (EBL) absorption. **The observed GeV break in the high state, as opposed to its absence in the low state, supports the notion that gamma-ray emission sites within or at the edge of the Broad Line Region (BLR) transition into fainter gamma-ray emission zones beyond the BLR.** Additionally, the coexistence of fast variability further supports that the high-energy emission region is mostly confined towards the edge of BLR.

Ultra-High-Energy Gamma-Ray Observation with the Tibet ASγ Experiment

Dr. Kazumasa Kawata

ICRR, University of Tokyo

Abstract

Cosmic rays are thought to be accelerated up to a few PeV by the most powerful sources, the so-called "PeVatron" in the Galaxy. On the other hand, gamma rays beyond 100 TeV are expected by the neutral pion decays caused by the interaction of these cosmic rays with the interstellar medium. Therefore, the gamma-ray observation is key to unveiling a long-standing mystery, the origin and the propagation of very-high-energy cosmic rays in the Galaxy, because gamma rays go straight unaffected by the magnetic field, pointing back to the sources.

The Tibet air shower (AS) array and the underground water-Cherenkov-type muon detector (MD) array have been successfully operating, at an altitude of 4,300 m in Tibet, China since 2014. The gamma-ray energy and arrival direction are determined by the surface AS array, while the underground MD array enables us to drastically suppress the background cosmic rays above 100 TeV, by means of counting the number of muons in an air shower. Using these Tibet AS+MD arrays, we have succeeded for the first time in observing gamma rays above 100 TeV from the Crab Nebula [Amenomori et al. PRL, 123, 051101 (2019)] and the Galactic plane [Amenomori et al. PRL, 126, 141101 (2021)]. In this presentation, we will review recent observations with the Tibet ASgamma experiment and discuss the most powerful cosmic-ray source "PeVatron" in our Galaxy.

The TAIGA-1 - a hybrid complex for gamma-ray astronomy, cosmic ray physics and astroparticle physics: first physical results and future plans

Professor Nikolay Budnev

Irkutsk State University

Abstract

The physical motivations and performance of the TAIGA (Tunka Advanced Instrument for cosmic ray physics and Gamma Astronomy) project are presented. The TAIGA astrophysical complex addresses ground-based gamma-ray astronomy at energies from a few TeV to several PeV and cosmic ray physics from 100 TeV to several EeV and astroparticle physics. The TAIGA approach is the cost effective way to construct a Cherenkov array with tens square kilometers area for gamma astronomy of super high energy. The pilot TAIGA-1 complex is located in the Tunka valley, ~50 km west of the southern tip of lake Baikal. At present time it includes a timing Cherenkov TAIGA-HiSCORE array with 120 wide-angle optical stations distributed over an area of about 1 square kilometer and four 4-m class Imaging Atmospheric Cherenkov Telescopes of the TAIGA-IACT array. The effective aria of the TAIGA-1 is about 0,9 km^2 for detection of gamma quanta with energy more than 100 TeV. There are three approaches to selecting gamma quanta from the hadron background in the TAIGA experiment: (1) IACT operation in standalone mode; (2) Stereo mode operation of two or more IACTs; (3) Hybrid mode operation -joint operation of TAIGA-HiSCORE and IACTs.. Present status of the project, the first experimental results including Crab nebula gamma emission energy spectrum in energy range 4 – 300 TeV reconstructed using TAIGA data in framework stereo and hybrid ways and plans for the constructing of the future 20 km^2 TAIGA array are presented.

New insight into the gamma-ray binary system HESS J0632+057

Miss Natalie Matchett, Prof. Brian van Soelen

University of the Free State

Abstract

Gamma-ray binaries, a small sub-class (only 9 known) of high mass X-ray binaries (HMXBs), consist of an O/Be type star and a compact object in the mass range of a black hole or neutron star. These systems continuously produce the majority of their non-thermal, multi-wavelength emission at energies greater than 100 MeV. The gamma-ray binary HESS J0632+057, consists of an undetected compact object in a ~317.3 day orbit around a B0 Vpe star. The X-ray and TeV lightcurves from this source display a double peak, which is believed to coincide with the compact object passing through the circumstellar disc of the Be star. However, this system lacks a clear orbital solution, as two incompatible solutions were obtained by Casares et al. (2012) and Moritani et al. (2018), which has made it difficult to interpret the observed emission. Long-term optical spectroscopic monitoring of HESS J0632+057 was undertaken with the High Resolution Spectrograph on the Southern African Large Telescope in order to trace the radial velocity of the system and the behaviour of the circumstellar disc of the Be star. During the last observing semester, for the first time, a third component was observed in the Balmer emission lines, giving an indication of structure in the disc and orbitally modulated disc behaviour. We present the latest results, covering ~70% of the orbit.

Non-thermal emission from local young massive stellar clusters and detection prospects

Dr Silvia Celli[1,2], Dr Alison Mitchell[3], Dr Giovanni Morlino[4], Dr Stefano Menchiari[4], Dr Andreas Specovius[3]

[1]Sapienza Università di Roma, Rome, Italy. [2]Istituto Nazionale di Fisica Nucleare - Sezione di Roma. [3]Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen Centre for Astroparticle Physics, Germany. [4]Istituto Nazionale di Astrofisica, Osservatorio Astrofisico di Arcetri, Florence, Italy

Abstract

Cosmic ray acceleration up to PeV energies has been suggested to take place in massive and young stellar clusters. The formation of a strong termination shock driven by the collective action of stellar winds in a compact cluster offers a promising location where efficient particle acceleration might take place. The subsequent hadronic collisions of these particles result into gamma-ray and neutrino production. Within a scenario of particle acceleration at the cluster wind termination shock, we compute the emerging gamma-ray and neutrino signals expected from the local young stellar clusters within the Milky Way, recently detected by GAIA. We further evaluate detection prospects of the emerging gamma-ray flux with the Cherenkov Telescope Array (CTA) and the Large High Altitude Air Shower Observatory (LHAASO).

The multiwavelength view of the gamma-ray binary PSR B1259-63/LS 2883

Prof Brian van Soelen[1], Prof Maria Chernyakova[2], Dr Denys Malyshev[3]

[1]University of the Free State. [2]Dublin City University. [3]University of Tübingen

Abstract

The gamma-ray binary PSR B1259-63/LS 2883 was the first radio pulsar discovered to be in a binary system with an early main sequence star. This source has subsequently been found to persistently produce unpulsed, non-thermal emission from radio up to very high energy gamma-rays every 3.4 years around the time of the periastron passage. Increases in the non-thermal radio, X-ray and likely TeV gamma-ray emission are found to coincide with the time of the pulsar crossing through the plane of the circumstellar disc surrounding the Be-type companion. However, at GeV energies, the source shows highly luminous, short time scale flares, between 40 to 80 days after periastron. During the last periastron passage we undertook a detailed radio, optical and X-ray campaign and, for the first time, detected a third peak in the X-ray emission as well as a break in the correlation between the radio and X-ray light curves. We present an overview of our multi-wavelength coverage of the 2021 periastrion passage, a proposed model for the third X-ray peak, as well as propsect for future observations.

LHAASO Observations on Pulsar Wind Nebula and TeV Halo

Dr. Ziwei Ou, Prof. Hao Zhou

Tsung-Dao Lee Institute, Shanghai Jiao Tong University

Abstract

Extended TeV sources associated with pulsars can be divide into two categories: pulsar wind nebula with TeV emission originating in the zone dominated by the pulsar; TeV halo with escaped particle diffusing into the ISM. The First LHAASO Catalog of Gamma-ray Sources found 35 sources with pulsar association. Based on it, we unveil the correlation between LHAASO sources and associated pulsars by spectral and morphological analysis. The observed properties of a PWN/TeV halo can be used to constrain the physical characteristics of the pulsar and surrounding environment. The spectral evolution of PWN/TeV halo shows that peak energy increase with pulsar age. Nebula and halo are explained in a unified scheme.

[8]8Department of Physics and Astronomy - MS 108, Rice University, 6100 Main Street, Hous- ton, Texas 77251-1892, USA

Abstract

Multi-wavelength observations have now led to the detection of about 50 'spider' binary systems - black widow and redback compact binaries differentiated by their companion's mass. In these systems, a millisecond pulsar heats and ablates its low-mass companion via the intense pulsar wind. The rich empirical phenomenology includes radio eclipses, optical light curves from the heated companion, as well as non-thermal X-ray and GeV light curves and spectra that point to the presence of relativistic leptons that have been accelerated at the intrabinary shock, as well as a hot companion. This represents an ideal environment for the creation of orbitally-modulated inverse Compton fluxes in the TeV band that should be within reach of current and future Cherenkov Telescopes. We have now included an updated synchrotron kernel, broken power-law injection spectrum, and a more realistic intrabinary shock geometry in our emission code to improve our predictions of the TeV flux. Our updated spectral and energy-dependent light curve outputs may aid in constraining particle energetics, wind properties, shock geometry, and system inclination of several spider binaries.

Surveying the gamma-ray sky with H.E.S.S.

Prof. Stefan Wagner

LSW, ZAH, U Heidelbr

Abstract

The H.E.S.S. telescope array in Namibia is an array of Imaging Atmospheric Cherenkov Telescopes (IACTs) with excellent sensitivity and angular resolution. Its large field of view facilitates sky surveys of the Southern gamma-ray sky. A wide range of surveys have been (and are being) performed with the H.E.S.S. telescopes, including, in particular, several surveys of the Galactic plane, the inner regions of the Milky Way, the Magellanic Clouds, pioneering surveys of the extragalactic sky, and time-domain surveys. The depths of these surveys varies from shallow, wide-field surveys to deep fields that mark the sensitivity limit of current generation gamma-ray instruments.

The surveys continue to provide the most successful search for new types of gamma-ray sources. They are pathfinders pinpointing interesting targets and permit statistical studies on source class properties, flux distributions and luminosity functions. The surveys led to the discovery of sources without counterparts in other waveband regimes (dark accelerators). Advanced analysis also permits studies of diffuse emission extending over areas that are considerably more extended than the 20 square degree field-of-view.

The talk will provide an overview of the survey projects carried out by the H.E.S.S. collaboration and present highlights of the different surveys. Case studies of the different use-cases will be illustrate the state of the art and future goals.

Global and local particle feedback on 3D PIC-RMHD simulations of astrophysical jets

Augusto Carvalho[1], Elisabete Maria de Gouveia Dal Pino[1], Tania Medina-Torrejón[2,1], Grzegorz Kowal[3]

[1]Institute of Astronomy, Geophysics, and Atmospheric Sciences, University of São Paulo. [2]Institute of Physics, University of São Paulo (São Carlos). [3]School of Arts, Sciences and Humanities, University of São Paulo (EACH-USP)

Abstract

In magnetically dominated regions of Astrophysical systems like the inner regions of relativistic jets, magnetic reconnection driven by turbulence has been lately invoked as a dominant particle acceleration mechanism. Previous works by our group analyzed this in 3D relativistic numerical simulations of blazars using the PLUTO and RAISHIN codes. It was found that particles can be accelerated up to ~ 10^18 eV when turbulent magnetic reconnection is present. However, in such cases the feedback of the particles into the background plasma was not accounted for. We compute such interaction by considering the work performed by the particles (component 1) and comparing it with that performed by the jet (component 2). This work is accounted for in terms of the Lorentz force of each component, and then a particle-to-jet work ratio is obtained. We consider a global ratio, meaning that the whole simulation domain with ~ 1.67 x 10^7 cells is taken into account, and a local one, where only the cells containing particles are accounted for, i.e. 4.7 x 10^4 cells. We consider jets with sigma ~ 1 and sigma ~ 10 to find that, in all cases, the average ratio is below zero in the regions where the energetic particles are localized, being more accentuated for the sigma ~10 case. Our results indicate that particle feedback is negligible. This result has strong implications on the derivation of the emission at very high energies in blazars and relativistic jets in general.

Misidentification of Short GRBs as Magnetars in Nearby Galaxies

Elisa Schösser

University of Heidelberg

Abstract

Time-domain astronomy is a rapidly growing field with ever more instruments dedicated to measuring transient events on the sky. As the number of observations grows, the likelihood of chance coincidences between these events or with temporally static astrophysical objects grows. In this young field, the proper statistical techniques to compute these chance coincident detection probabilities do not yet fully exist.

We examined one such association to derive its misidentification probability: Recent observations of GRB 200415A and 231115A, short and very bright pulses of gamma-rays, have been claimed to be extragalactic magnetar giant flares (MGF) as their origins were associated with the nearby galaxies NGC 253 and M82. However, as the redshifts of the transient objects were not measured, it is possible that the measured locations of the transients on the celestial sphere and the location of the local galaxy merely coincided. Thus, their real progenitors could have been arbitrarily far away, leaving the standard model of short gamma-ray bursts (SGRBs), the merger of two compact objects, as an explanation for the observations. We estimate the false-alarm rate of SGRBs being incorrectly identified as MGFs using population synthesis.

Physically motivated emission model for high-state blazar emissions powered by magnetic reconnection

Juan Carlos Rodríguez-Ramírez[1], Elisabete de Gouveia Dal Pino[2], Ulisses Barres de Almeida[1]

[1]Brazilian Center for Research in Physics (CBPF). [2]Instituto de Astronomia, Geofísica e Ciências Atmosféricas, Universidade de Sao Paulo (IAG-USP)

Abstract

Blazars are widely acknowledged as extragalactic particle accelerators and promising candidates for producing ultra-high-energy cosmic rays (UHCRs). However, the mechanism(s) responsible for blazar high-energy (HE) emission, as well as the region(s) within the blazar jet where particle acceleration occurs, remain open questions. In this context, peculiar features exhibited by blazars during high states could provide key constraints on their nature as particle accelerators. Here we present a physically motivated model for blazar emission powered by magnetic reconnection along the transition from magnetic to kinetic-dominated flow in the blazar jet. With this model we reproduce the multi-messenger spectrum of the blazar TXS0506+056, as well as TeV spectral spikes like the one observed in the historical X-ray high state of Mkr 501. Based on our data fitting, we constrain the location of the particle acceleration regions in the jet and show that very and ultra high energy cosmic-rays can be produced under such a scenario.

Search for dark matter subhalo candidates in the fourth Fermi-LAT catalog with kernel Mahalanobis distance methods

Dr. Kenji Yoshida

Shibaura Institute of Technology

Abstract

The fourth Fermi-LAT catalog (4FGL) lists 7195 gamma-ray sources. Among these sources, 4767 gamma-ray sources have been identified/associated with blazars, pulsars, and other source types, while there are still 2428 gamma-ray sources yet to be identified, constituting approximately 34% of the aggregate. Various machine learning and deep learning methods have been reported to classify these unidentified gamma-ray sources in the Fermi-LAT catalog. The present study involves the application of kernel Mahalanobis distance methods to spatial, spectral, and temporal features of gamma-ray sources listed in 4FGL. The evaluation encompasses the classification performance concerning blazars, pulsars, and other source types, alongside outcomes pertinent to classifying unidentified gamma-ray sources. Leveraging the robust discriminatory capabilities of the kernel Mahalanobis distance methodology in isolating anomalies, we explore potential gamma-ray sources as candidates for dark matter subhalos, whose annihilating or decaying gamma-ray signals could appear as gamma-ray sources without detectable counterparts at other wavelengths. The results of our study might be of interest for follow-up searches with IACTs and the CTA.

Effects of Cosmic Ray Bounce Diffusion in Highly Turbulent and Magnetized Environments

Lucas Barreto-Mota[1], Elisabete M. de Gouveia Dal Pino[1], Siyao Xu[2], Alexandre Lazarian[2]

[1]Universidade de São Paulo. [2]University of Wisconsin, Madison

Abstract

Cosmic rays interacting with the turbulent interstellar medium (ISM) produce non-thermal emissions and secondary particles, observable from Earth. However, understanding their diffusion and acceleration within the ISM remains a complex scientific challenge. This work investigates the effects of bounce diffusion and scattering using new theoretical and observational insights.

We combine three-dimensional magnetohydrodynamic (MHD) simulations of star-forming regions with test particle simulations to study particle diffusion. Our findings reveal that while MHD turbulence alters overall particle diffusion, particles are not simply trapped in magnetic mirrors. Instead, their parallel diffusion is affected, while perpendicular diffusion continues due to the super-diffusion of the magnetic field.

In general, we find that bounce diffusion (Lazarian & Xu 2021) plays a significant role in the parallel diffusion of particles. Notably, diffusion can be affected by the initial particle pitch angle, especially if resonant scattering is somehow suppressed. Particles with larger initial pitch angles take longer to diffuse parallel to the magnetic field, highlighting the need to revise conventional diffusion coefficients used in the ISM and around sources.

Our calculations suggest a diffusion coefficient of ~10^{27}cm^2/s for particles with energies of the order of 100 TeV, aligning with HAWC gamma-ray observations around pulsars like Geminga. These results will be incorporated in forthcoming studies of diffuse gamma-ray emission in molecular clouds and massive star formation regions.

Development of a Lake Array Proposal for SWGO

Dr. Ziwei Ou, Mr. Tianyang Li, Prof. Hao Zhou

Tsung-Dao Lee Institute, Shanghai Jiao Tong University

Abstract

The Southern Wide-field Gamma-ray Observatory (SWGO) is a proposed next-generation gamma-ray survey experiment with high sensitivity and a wide field of view. Covering the southern sky, it will be built in South America to complement HAWC and LHAASO in the Northern Hemisphere. We designed a lake array proposal for SWGO to record particles from extensive air showers initiated by high energy gamma-rays. It would consist of two types of detectors: surface detectors and muon detectors. Surface detectors will be placed on the lake for the detection of electromagnetic particles. They are small tanks filled with water and equipped with a photomultiplier tube (PMT) at the bottom. Muon detectors will be deployed underwater, where lake water will be a natural filter to absorb electromagnetic components while allowing the measurement of muon particles. A lake array is being proposed for SWGO motivated by advantages over ground-based arrays, such as lower cost, fewer constraints on the detector shape, and electromagnetic component rejection for muon detectors, which create more possibilities to optimize detectors and the array. A number of technological solutions are being proposed for the implementation of SWGO, including both lake- and ground-based arrays, and a final decision on the adopted technology is expected soon, with the conclusion of the project's R&D phase.

TAIGA - detection of the Crab Nebula using a random forest analysis of TAIGA IACT data

Dr Martin Tluczykont[1], Dr. Razmik Mirzoyan[2]

[1]University of Hamburg. [2]MPPMU

Abstract

TAIGA (Tunka Advanced Instrument for cosmic ray and Gamma-ray Astronomy) has implemented a new, hybrid observation technique, based on a combination of the imaging air Cherenkov telescope (IACT) technique, and the HiSCORE timing array concept. Our aim is to explore gamma-ray sources at energies of a few 10s of TeV to several 100 TeV, an energy range particularly important to spectrally resolve the cutoff regime of the galactic Pevatrons. TAIGA currently consists of an array of 121 wide angle (0.6 sr) air Cherenkov timing stations distributed over an area of the order of 1 square-km and three IACTs with a diameter of 4.75 m and a field of view of 9.7∘.

Two independent reconstruction and analysis chains were implemented within the TAIGA collaboration. In this contribution, the current status of one of these analysis chains is discussed and the detection of the Crab Nebula, with the first IACT in operation, are presented.

A new air shower array experiment ALPACA in Bolivia to explore sub-PeV gamma-ray astronomy in the southern sky

Dr. Sei Kato for the ALPACA Collaboration

Institute for Cosmic Ray Research, The University of Tokyo

Abstract

ALPACA (Andes Large-area PArticle detector for Cosmic-ray physics and Astronomy) is a new air shower array observatory to be constructed in Mt. Chacaltaya, Bolivia in 2025. It mainly focuses on the discovery of astrophysical accelerators of Galactic PeV (= 10^{15} eV) cosmic rays called PeVatrons through the observation of sub-PeV (> 10^{14} eV) gamma rays from celestial sources in the yet-unexplored southern sky. The observatory has two components: a surface air shower array (AS array, 83,000 m^2) composed of 401 plastic scintillation detectors and an underground muon detector array (MD array, 3,600 m^2) containing water. The AS array captures air shower particles produced by primary cosmic rays and gamma rays in the atmosphere and reconstructs their energies and arrival directions. On the other hand, the MD array records the Cherenkov light signals given by air shower muons produced as a consequence of the hadronic interaction, leading to great improvement in the sensitivity of the observatory to primary gamma rays. The prototype array called ALPAQUITA has already been constructed and started data taking in September 2022 and its performance is studied from the observation of the cosmic-ray Moon's shadow. ALPAQUITA is also to be equipped with an MD in 2024 to improve its sensitivity to gamma-ray sources, and the work for the construction is now ongoing. This presentation gives an overview of the gamma-ray astronomy promoted by ALPACA and the current results of the ALPAQUITA data analysis.

Abstract

Investigating variability of Active Galactic Nuclei (AGN) sources is crucial for understanding particle acceleration processes and the magnetic-field behavior in those compact objects. AGNs are highly variable, with non-thermal emission in all wavelengths, which is generally attributed to relativistic particles accelerated in shocks or magnetic reconnection regions along the jet. In this study, we conduct statistical analyses, focusing on variability, utilizing the latest release of the Fermi-LAT catalog (4LAC). We correlate this variability with the detected AGN population to enhance measurement prospects for the Cherenkov Telescope Array (CTA), in order to extrapolate them to the VHE gamma-ray band and to produce synthetic SEDs and light-curves of selected AGNs to make predictions for the forthcoming CTA and ASTRI Mini-Array facilities.

Our analysis encompasses 3814 AGN sources selected from the catalog, examining parameters such as Fractional Variability and Excess Variance across three typical SED classes observed in blazars. Supplementing the annual and 2-month data provided in the 4LAC catalog, we have extended this variability study using the complementary public Fermi-LAT light curve repository, providing information for 3-day, weekly, and monthly intervals.

Moreover, we curate a subset of the catalog targeting AGN sources for detecting flares within CTA's gamma-ray spectral range. Our collaboration with the WG Redshift determination, AGN Population and AGN Variability Task Forces within the CTA aims to define a comprehensive target population of very high-energy objects. By bridging Fermi-LAT observations with CTA's capabilities, we strive to advance our understanding of AGN variability and its implications for the CTA extragalactic survey.

Search of dark matter annihilation in stellar streams with the Fermi LAT

Cristina Fernández-Suárez, Dr. Miguel Ángel Sánchez-Conde

IFT (UAM-CSIC)

Abstract

In this talk, I will present our current research on stellar streams as a new and complementary target for dark matter (DM) indirect searches with gamma rays. The aim of this project is to unveil the unknown properties of the DM using stellar streams, which are astrophysical objects never used before in this context. Stellar streams form when a satellite, such as a dwarf galaxy (dG) or a globular cluster (GC), is tidally disrupted by the gravitational potential of its host galaxy. In particular, those streams whose progenitor is a dG are particularly intriguing targets for indirect DM searches, since dGs are thought to be highly DM-dominated systems. We expect them to have lost most of their DM content during the stretching process, but still contain a non-negligible amount of DM within their core. If the DM particles are Weakly Interacting Massive Particles (WIMPs), they could annihilate in the streams' core, producing a detectable gamma-ray signal. We analyze data from the Fermi LAT looking for a potential annihilation signal of WIMPs from the direction of some selected stellar streams, and use the results to place constraints on the DM parameter space.

Gamma-ray bursts at Very High Energy: Clues from their host environments

Dr. Antonio de Ugarte Postigo[1,2], Dr. Jean-Gregoire Ducoin[3]

[1]CNRS / OCA. [2]CNRS / LAM. [3]CPPM

Abstract

Gamma-ray bursts (GRBs) begin to be regularly detected by Cherenkov telescopes at the TeV range. It has been discussed if the local environment in which the explosion is produced may play a role in the production of these VHE photons.

Here I will present a systematic study of the host environment of GRBs detected at VHE with Cherenkov telescopes. We observed the host galaxies in optical and IR and derived the host galaxy properties from spectral energy distribution fits. These results are complemented with broad-band and spectroscopic observations of the afterglows. Comparing with the general sample of GRB host galaxy environments, we search for peculiarities, such as large circumburst densities or local dust content. With the conclusions of this study we will verify emission mechanisms and discuss future expectations for VHE GRB observations.

Perspectives on the Future Developments of Ground-Based Gamma-ray Astronomy

Dr Ulisses Barres de Almeida

Brazilian Center for Physics Research (CBPF)

Abstract

Ground-based gamma-ray astronomy is a powerful tool to study cosmic-ray physics, providing a diagnostic of the high-energy processes at work in the most extreme astrophysical accelerators of the universe. Ground-based gamma-ray detectors apply a number of experimental techniques to measure the products of air showers induced by the primary gamma-rays over a wide energy range, from about 30 GeV to few PeV. These are based either on the measurement of the atmospheric Cherenkov light induced by the air showers, or the direct detection of the shower's secondary particles at ground level. After decades of continuous developments and breakthroughs, and thanks to the recent achievements of new and highly sensitive ground-based gamma-ray detectors, important scientific results are emerging which motivate new experimental proposals, at various stages of implementation. In this talk I will present the current expectations for future experiments in the field and discuss its synergies and impact to other areas of modern astronomy.

Status of the ASTRI mini-array gamma-ray experiment: technology and science using wide-field aplanatic IACT telescopes

Dr Giovanni Pareschi

INAF - Osservatorio Astronomico di Brera

Abstract

The ASTRI program was launched 10 years ago to develop small-sized dual-mirror aplanatic wide-field IACT telescopes as a precursor to the array of small-sized telescopes (SSTs) for the Cherenkov Telescope Array (CTA) observatory's southern site. The program initially received INAF and MUR (the Italian Ministry for Universities and Research) support. Still, it gained support from other international partners such as the University of Sao Paulo/FAPESP, Nort-West University/South Africa, IAC, FGG, and Université de Geneve at different project stages. The program's first significant achievement was the development of the end-to-end ASTRI-Horn prototype and its installation at the INAF site of Serra La Nave. The prototype featured an innovative compact camera based on SiPM sensors. It proved the dual-mirror Schwarzschild-Couder optical configuration as an aplanatic system while detecting the Crab Nebula in gamma rays. The telescope underwent significant refurbishment and is now used to observe the volcano's bright gamma-ray sources, cosmic rays, and muon radiography studies. Meanwhile, the ASTRI mini-array is being implemented in Tenerife to study the gamma-ray sky in the 1-100 TeV energy band with unprecedented angular resolution (3 arcmin), which complements astroparticle arrays like LHAAZO perfectly. This talk discusses the project's status, scientific goals, and expectations.

Cosmic Ray Propagation and Multi-Messenger Emission by Galaxy Clusters

Stela Adduci Faria[1], Rafael Alves Batista[2], Prof. Elisabete de Gouveia Dal Pino[1]

[1]Instituto de Astronomia, Geofísica e Ciências Atmosféricas - USP. [2]Sorbonne Université, Institut d'Astrophysique de Paris

Abstract

Non-thermal processes taking place in the intracluster medium (ICM) can provide important insights into the properties and dynamics of galaxy clusters. Particles accelerated either by shocks in the ICM or by sources in the clusters can interact with the surrounding medium, resulting in the production of high-energy particles such as gamma rays and neutrinos. Detection of gamma-rays and neutrinos from galaxies within clusters would represent a crucial advancement in our understanding of the processes involved in particle acceleration within the intra-cluster medium (ICM) and the confinement of cosmic rays. Previous studies have identified these large structures as potential sources for confining and accelerating particles to high energies. We present results of a detailed Monte Carlo simulation of cosmic-ray propagation using cosmological MHD simulations of a Coma-like cluster, which we use to predict fluxes of gamma rays and neutrinos. We inject CRs with energies in the range 10^{14} to 10^{19} eV, and follow their cascading over the entire cluster obtaining precisely their gamma-ray and neutrino fluxes associated with high-resolution individual clusters. This work will be able to reproduce more realistic observed gamma-ray and neutrino emissions, providing constraints for observing cluster targets.

The variability of 8 blazar candidates among the Fermi-LAT unidentified gamma-ray sources

Dr Pheneas Nkundabakura

University of Rwanda College of Education

Abstract

We discuss the time-series behavior of 8 extragalactic 3FGL sources away from the Galactic plane (i.e., $|b| \geqslant 10°$) whose uncertainty ellipse contains a single X-ray and one radio source. The analysis was done using the standard Fermi ScienceTools, package of version v10r0p5. The results show that sources in the study sample display a slight indication of flux variability in γ-ray on monthly timescale. Furthermore, based on the object location on the variability index versus spectral index diagram, the positions of 4 objects in the sample were found to fall in the region of the already known BL Lac positions.

The Very High Energy Gamma Ray Burst GRB190114C asobserved by MeerKAT

Mr Reikantseone Diretse

Inter-University Institute for Data-Intensive Astronomy, Department of Astronomy, University of Cape Town

Abstract

I present the MeerKAT study of the highly energetic gamma ray burst (GRB), GRB190114C, which was the first GRB to have been recorded at teraelectronvolt (TeV) energies by the MAGIC telescopes in 2019. We have observed this GRB with the MeerKAT radio telescope from as early as within the first day of the burst event, up to nearly a year at over 350 days. Our 13 epoch light curve is the most sampled radio light curve of this GRB

at low frequencies (1.28 GHz) in comparison to published results. I detail the evolution of GRB190114C as a forward shock in a homogeneous medium for about 100 days post-burst, followed by a jet-break likely occurring simultaneously with the passage of the characteristic peak frequency across the observing band. I

constrain the host galaxy component, and compare our modelled host value to fluxes extrapolated from the only existing pre-burst radio images of the field. As it is often for GRB observations at low radio frequencies, the evolution of GRB190114C is highly affected by strong interstellar scintillation, which I quantitatively constrain as long lasting refractive scattering. I then use the calculated scintillation parameters to put an upper limit on the radial size of the fireball, and compare this to other GRBs.

Historical Overview of Ground-based Gamma-ray Astrophysics

Dr Razmik Mirzoyan

Max-Planck-Institute for Physics (Werner-Heisenberg-Institut). National Academy of Sciences of Republic Armenia

Abstract

The ground-based technique for imaging atmospheric Cherenkov telescopes is a rapidly developing, powerful branch of astrophysics. Fundamental questions in astrophysics, astroparticle physics, cosmic rays and cosmology are at the heart of this technology. The discipline has made remarkable progress since the discovery of the Crab Nebula, the first source of gamma rays, 35 years ago. Thanks to this technique, over 250 very high-energy gamma ray sources of galactic and extragalactic origin have been discovered. Current highly sensitive telescopes are capable of detecting a point source 100 times fainter than the standard candle, the Crab Nebula, in 25 hours of observation. The development of this technology led to the Cherenkov Telescope Array (CTA), the next-generation large-scale instrument. This report presents a brief history of ground-based astrophysics using very high-energy gamma rays.

Synergies between air shower array detectors and imaging Cherenkov telescope arrays

Dr Roberta Zanin

Cherenkov Telescope Array Observatory gGmbH

Abstract

Very high-energy gamma-ray astrophysics provides unique observations of the unexplored Universe at VHEs – a region of the electromagnetic spectrum covering four decades in energy above 20 GeV. This is an exciting field covering a very wide range of scientific themes from fundamental physics to cosmic ray physics and astrophysics related to the most extreme processes. This is the last among the non-thermal astronomical fields to have emerged and, since its establishment, it led to the discovery of more than 200 sources at VHEs.

Two detection techniques have been proven efficient in the observation the VHE sky: the imaging Cherenkov and air shower detection. Although they have a large overlap in the covered energy range, each of them has its own main energy domain: the imaging Cherenkov telescope array can observe down to few tens of GeV up to hundreds of TeV with the best sensitivity at around 1 TeV, whereas the air shower detector arrays have a higher energy threshold but are more sensitive at energies above few tens of TeV.

In this talk I will be describing the different and the common capabilities of these two detection techniques, proving their complementary nature. I will be referring to the current and upcoming facilities of the two kinds, including, among others, the Cherenkov Telescope Array Observatory as well as the HAWC and SWGO shower array detectors. The key takeaway is that the future of astronomy can substantially benefit from these harmonised observing techniques.

Recent highlights from the Large High Altitude Air Shower Observatory (LHAASO)

Prof. Hao Zhou

Tsung-Dao Lee Institute, Shanghai Jiao Tong University

Abstract

The Large High Altitude Air Shower Observatory (LHAASO), located in China at 4410m above sea level, is a hybrid extensive air shower detector array. Utilizing different detection techniques, LHAASO monitors the northern gamma-ray sky from a few hundreds of GeV to beyond PeV energies. LHAASO has been fully operational since July 2021. Recently, the first LHAASO catalog published 90 gamma-ray sources. 43 of them are PeVatron candidates with gamma-ray emission above 100 TeV. Among these sources, a giant gamma-ray bubble with energy up to 2 PeV is detected in the Cygnus region, indicating a super-PeVatron cosmic-ray accelerator that is likely associated with young massive star cluster Cygnus OB2. These findings confirmed the existence of PeV cosmic-ray accelerators in our Galaxy and opened up an era of ultra-high-energy gamma-ray astronomy. On Oct 9, 2022, the brightest gamma-ray burst ever seen in history happened in the field-of-view of LHAASO. Tens of thousands of very-high-energy gamma-ray photons were recored. We will summarize the status of the LHAASO experiment and present recent highlights from the LHAASO observatory in this talk.

Probing Fundamental Physics phenomena with Wide-field Ground-based Gamma-ray telescopes

Prof. Dr. Aion Viana

Instituto de Física de São Carlos - Universidade de São Paulo (IFSC-USP)

Abstract

High-energy gamma rays offer unique insights into Particle Physics phenomena beyond the Standard Model of Particle Physics. This complements research conducted in dedicated laboratory experiments and particle accelerators. Notably, intense gamma-ray emissions may result from the annihilation, decay, or other interactions of non-baryonic Dark Matter in the dense environments of the Universe. Wide-field ground-based telescopes have the capability to detect gamma rays ranging from hundreds of GeV up to the PeV range. They represent the most sensitive detectors of gamma ray fluxes for energies above tens of TeV. With an almost 100% duty cycle, these telescopes can observe approximately 2/3 of the sky daily, presenting a significant discovery opportunity in fundamental physics. In this talk I will review the extensive research program conducted by these facilities in the quest for new Physics. Apart from the search for signals from Dark Matter across various targets, there exists the tantalizing prospect of detecting Axion-Like Particles, Primordial Black Holes, and finding evidence of Lorentz Invariance Violation associated with possible quantum gravity effects at the Planck scale. A highlight of the latest and most sensitive results from the current generation of telescopes, including LHAASO, HAWC, and the Tibet AS-gamma, will be presented. Finally, in the light of the future Southern Wide-Filed Gamma-ray Observatory (SWGO), the prospects and strategies in the search for physics beyond the Standard Model will be discussed.

Gamma-Ray Bursts at High Energies and Multi-messenger Connections

Susumu Inoue

ICRR, U Tokyo

Abstract

Gamma-ray bursts (GRBs) are the most luminous explosive phenomena in electromagnetic radiation, believed to be triggered by certain types of stellar core collapse events and compact binary mergers. However, many of their basic physical aspects remain poorly understood, such as the nature of the central engine, and the mechanisms of jet formation and prompt radiation. Recent detections of TeV gamma rays from various types of GRBs by Cherenkov telescopes and air shower arrays shed new light on the physics of jet formation, energy dissipation and particle acceleration in GRBs. We discuss the current status of the field and prospects for further progress with future instruments, including multi-messenger connections with gravitational waves, cosmic rays and neutrinos.

Neural Networks Unveiling Filamentary Structures in the Interstellar Medium: A Multi-Wavelength Approach Integrating Data from Advanced Telescopes

Dana Alina, Adai Shomanov

Nazarbayev University, Astana, Kazakhstan

Abstract

Our study employs neural networks, such as Mask-RCNN and Unet, to the identification of filamentary structures of the interstellar medium (ISM), and particularly, their position angle which is essential in linking the ISM structures to the ISM magnetic field. We integrate diverse datasets from various facilities, including the atomic hydrogen survey HI4PI, Herschel and Planck space telescopes to create a comprehensive and multi-wavelength perspective. The integration of these datasets is essential for a holistic understanding of the ISM, as Filamentary molecular clouds are key stages in the star formation process, at large, of the order of a parsec, and small, of the order of thousands au.

In our presentation, we will highlight the significance of treating extensive datasets that are provided by JWST, ALMA, MeerKAT, and ASKAP intelligently, emphasizing the pivotal role of neural networks, particularly our proposed model, in extracting meaningful information.

Moreover, molecular and atomic gas data bares significant information about the interstellar magnetic fields, through the anisotropic turbulent properties and magnetohydrodynamic nature.

Thus, we will discuss how the wealth of data from these facilities contributes to a more comprehensive view of star formation processes. Our work underscores the synergy between advanced observational facilities and innovative data analysis techniques, paving the way for a deeper understanding of the fundamental processes shaping our galactic environment.

Shocks and Dark Gas in Diffuse Interstellar Clouds

William Reach[1,2], Carl Heiles[3]

[1]Space Science Institute. [2]Universities Space Research Association. [3]University of California, Berkeley

Abstract

Interstellar clouds have more material than is traced by the 21-cm line of atomic hydrogen, as evidenced by far-infrared/submm observations since the late1980s, when we identified a sample of high-latitude "cirrus" clouds for detailed study. The clouds have masses of order 100 solar masses and are within 1 kpc of us. The dense cloud cores have detectable CO, while larger portions of the clouds are also molecular, in a balance between molecule formation on dust grains and dissociation by the interstellar radiation field. Using Planck, GASS, and Arecibo observations, we assessed the clouds' contents and showed that many of them are composed largely of CO-dark molecular gas. A pair of clouds, G228.0-28.6 and G230.1-28.4, has proportions of Atomic:Dark:CO-bright gas of 2:1:0.9 and 0.1:1:0.1, respectively. Examining the cloud structure at the best spatial resolution available, using mid-infrared (WISE) and optical images reveals potential shock fronts at the leading edge of their apparent motion through the lower-density inter-cloud medium. The CO-dark gas may be closely related to these shocks, having formed in the cooled, compressed gas behind the shocks.

Using Gas-rich Early-type Galaxies to Test Empirical and Theoretical Models of Molecule Formation

Debra Dunham[1], Krislyn Sourivong[1], Dr. Danielle Lucero[1], Dr. Lisa Young[2]

[1]Virginia Tech. [2]University of Illinois Urbana-Champaign

Abstract

We present an update on work which uses high resolution observations of CO (CARMA: 3") and HI (JVLA; 6") in early-type galaxies to stress test existing empirical and first principle physical models of molecule formation. These existing models are being used as input into semi-analytic models of galaxy evolution. A good model should have applicability and predictive power beyond the ranges of conditions that are found in nearby spirals. Compared to disk galaxies, early-type galaxies have different gas contents, stellar populations, and evolutionary histories. Early-type galaxies also have a much wider range of HI/H_2 mass ratios than spirals. Additionally, early-types' central stellar densities are typically larger than those observed in disk galaxies, which translates to larger central pressures. For all of these reasons, the early-type galaxies provide complementary tests of HI/H_2 physics to that done for disk galaxies. The HI data presented in this work comprises the highest resolution HI data for a large sample of early-type galaxies to date.

Impact of Protostellar jets on the ambient medium in infrared and radio

Dr. Sarita Vig[1], Amal Cherian[2], Dr. Sreelekshmi Mohan[2,3]

[1]Indian Institute of Space science and Technology, (IIST), Thiruvananthapuram, Kerala, India.
[2]Indian Institute of Space science and Technology (IIST), Thiruvananthapuram, Kerala, India.
[3]Istituto Nazionale di Astrofisica-Osservatorio Astronomico di Capodimonte Napoli (INAF-OACN), Napoli, Italy.

Abstract

Protostellar jets, launched in the early evolutionary phase of young stellar objects, are targets of intense scrutiny to understand the properties of young protostars. We have investigated a few jets from massive embedded protostars through their interaction with the ambient medium, in radio and infrared wavebands and we trace emission from shocked regions where the jet impacts the medium. Our near-infrared measurements that include [FeII] and [H_2] transitions in the near-infrared have been utilised to probe the nature of shocked gas. We comment on the emission mechanism on the basis of the morphological co-location of emission from these two tracers, both near as well as far from the jet. Our results from the Giant Metrewave Radio Telescope (GMRT), India, at low radio frequencies have confirmed the presence of non-thermal synchrotron emission from these jets, unlike measurements at higher radio frequencies that usually trace thermal free-free emission. We assimilate the observed radio emission measurements within a numerical model that we have developed, which incorporate the effects of both thermal and non-thermal emission, to understand the properties of the jets and ambient medium in the vicinity. Finally we compare the emission from molecular, atomic and ionised gas in infrared and radio to decipher and comprehend the properties of the massive protostellar systems such as the mass-loss rate of the jets. We find that the values are higher than those observed for jets from low mass protostars.

ISM energy balance and structure formation over cosmic time through simulations and observations

Fatemeh Tabatabaei[1], Maryam Khademi[1], Hossein Hatamnia[1], Reyhaneh Javadi[2]

[1]Institute for Research in Fundamental Sciences-IPM. [2]Bonn University

Abstract

Investigating the thermal and non-thermal processes in the ISM of galaxies is vital to understand their evolution over cosmic time. Radio observations in nearby galaxies indicate that the non-thermal processes in which turbulence, magnetic field, and cosmic rays are involved can affect the formation of gas clouds and stars. They can also help the onset of winds and outflows in galaxies. These can be further investigated over cosmic time by combining radio and optical/near-infrared observations of galaxies. The James Web Space Telescope resolves the evolution of thermal processes by mapping ionized gas and dust in galaxies. This information combined with the upcoming surveys with the Square Kilometer Array (SKA) and ngVLA will make a major breakthrough in mapping the non-thermal processes and understanding their role in the evolution of stars and their host galaxies. Our simulations show that, already in its first phase of construction, the SKA will be able to trace the evolution history of spiral galaxies such as M51 and NGC6946 back to cosmic noon. This study indicates the important role of the non-thermal pressure in driving winds and outflows at high-z. We further address these through observations of a sample of star forming galaxies in the COSMOS field, as members of the MeerKAT International GHz Tiered Extra-galactic Exploration (MIGHTEE). We find that both cosmic rays and magnetic fields were more energetic at higher redshifts ($z<5$). Comparing these results with thermal gas pressures would add valuable insight into the subject.

Detection of Self-Enrichment in Young Massive Star Clusters Using 26Al Tracers

Katarzyna Nowak

Centre for Astrophysics Research, University of Hertfordshire

Abstract

Self-enrichment is one of the leading explanations for chemical anomalies in globular clusters. In this scenario, a certain polluter star, enriches a forming cluster with its yields, likely ejecting radioactive ^{26}Al into its surroundings. Detection of ^{26}Al in young massive star clusters holds significant implications, potentially supporting the self-enrichment scenario if these clusters are indeed progenitors of globular clusters. Recent advancements in observational techniques, including detections of the 1.8 MeV and 511 keV ^{26}Al decay gamma ray lines, as well as ^{26}AlF molecules or positronium radio recombination lines, suggest promising avenues for detecting ^{26}Al and maturing detection methods.

In this talk, I will focus on examining a sample of young massive star clusters in the nearby Universe, where self-enrichment could plausibly occur. Despite optimistic scenarios, detecting most sources remains challenging with some methods. However, we identify R136 in the Large Magellanic Cloud as a promising candidate for such investigations. Although the best-case scenario for detecting a 1.8 MeV signal may require several years with instruments like COSI, the feasibility of detecting ^{26}AlF with the ALMA telescope in several candidate clusters offers encouraging prospects for further study and understanding of self-enrichment scenario in young massive star clusters.

Star formation drivers in the local universe

Dr. Edvige Corbelli

INAF-Osservatorio Astrofisico di Arcetri

Abstract

The ALMA MaNGA QUEnching and STar formation survey (ALMaQUEST) has provided a sample of 66 galaxies, including interacting galaxies, where the cold and warm ISM has been mapped at 2.5 arcsec resolution (1-6~kpc). A recent analysis of this sample (Ellison..Corbelli ..et al. 2023) points out the delicate balance between local feedback effects (Ostriker & Kim 2022) and non local dynamical effects (Krumholtz et al. 2018) in regulating the formation of molecular clouds and stars. To improve our understanding of the overall proccess that drives the formation of stars across galaxy disks, as galaxies evolve, we are investigating a highly resolved galaxy in our neighborhood, M33, and a sample of galaxies in the MANGA sample of similar or lower mass than M33, thus extending the analysis to a lower mass range than the ALMaQUEST sample. M33 has evolved in isolation, as shown by numerical simulations of its disk along the past orbit (Corbelli and Burkert 2024 A&A in press), and we can benefit of a complete multiwavelength coverage, in addition to very high resolution recent JWST results (Peltonen et al. 2024) and MUSE data of its southern arm. The physical processes that link the birth of Young Stellar Clusters and massive protostars, as well as the formation of molecular clouds (Corbelli et al. 2017,2019), to the global and local dynamical properties of the ISM will be analyzed and compared with data for the ALMaQUEST sample and with theoretical predictions (Corbelli et al. in preparation).

Unveiling the cold outflow from the nucleus of the Milky Way

Enrico Di Teodoro[1], Jay Lockman[2], Naomi McClure-Griffiths[3], Lucia Armillotta[4]

[1]University of Florence. [2]Greenbank Observatory. [3]Australian National University. [4]Princeton University

Abstract

The nucleus of our Galaxy is home of several high-energy processes (black hole, intense star formation) that have generated a large-scale, multiphase, nuclear wind. In the past few years, I have extensively studied the colder components of this outflow thanks to dedicated surveys of the Galactic Centre region in neutral hydrogen (HI) and molecular lines. These observations have revealed for the first time the resolved structure of cold gas clouds entrained in a galactic wind and have returned a number of new, puzzling aspects of these fascinating phenomena. In this talk, I will review the main discoveries and findings about the cold gas phases of the Milky Way's nuclear outflow and I will discuss its possible origin and impact on the central regions of the Galaxy.

Observations of LMC Coronal Gas and a Multiphase CGM

Dhanesh Krishnarao

Colorado College

Abstract

Recent measurements of a relatively high mass for the LMC imply that it should host a massive Corona, a collisionally ionized, warm-hot gaseous halo at the virial temperature (∼10^5.4K) initially extending out to the virial radius (100 - 130 kpc). Such a Corona would have shaped and fed the formation of the Magellanic Stream (e.g. Lucchini et al. 2020, Nature). We have found direct observational evidence for this Corona via highly ionized oxygen (O VI), and indirect detections via C IV and Si IV, seen in UV absorption toward background quasars using data from HST and FUSE (Krishnarao et al. 2022, Nature). We find that the Corona is part of a pervasive multiphase CGM seen in many ionization states with a declining projected radial profile out to at least 35 kpc from the LMC and a total ionized mass of log(M/M⊙) = 9.1 ± 0.2. Finding the Corona is a crucial step forward in characterizing this infalling Group and its nested evolution with the Local Group and helps diagnose the impact of galactic-scale winds emerging from star formation feedback in the LMC. The complex CGM will also be present in absorption line studies of stars in the LMC observed through the ULYSSES HST program, many of which are being detected through our ongoing work from an HST Legacy Archival Program. In addition, we are exploring the cooler phases of gas in this complex CGM environment that could condense onto the stream, MCs or Milky Way to trigger star formation.

Constraining star cluster formation using multiwavelength observations with JWST and HST

Ms Jianling Tang, Dr Kathryn Grasha, Dr Mark Krumholz

The Australian National University

Abstract

The physical processes that govern the formation and evolution of star clusters are encoded in the distributions of star cluster physical properties, such as their mass and age functions. These functions hint at the physics underlying how star clusters form, evolve, and die. The largest obstacle to measuring these functions from JWST and HST observations is that current analysis methods require us to discard light clusters, which are by far the most numerous, because they are susceptible to luminosity fluctuations due to their small numbers of stars. This talk will introduce a novel method that solves the problem of deriving cluster demographics from integrated light without the need to discard most of the data, yielding the largest and most complete description of star cluster demographics to date, derived from ~10,000 clusters in ~40 galaxies, spanning a wide range of star-forming environments. These results constrain the evolution and dispersion of star clusters and their dependence on properties such as host galaxy star formation rate and surface density. Our method also allows us to probe the initial cluster mass function using clusters so young that they are embedded in dust and only visible in the IR with JWST, a population that may reveal insights into the physics of cluster formation in the early universe and the origins of present-day globular clusters.

Star formation and molecular gas observations of NGC 5331 with VLA and ALMA

Devaky Kunneriath[1], Loreto Barcos Munoz[1], Alejandro Saravia[2], Eduardo Rodas-Quito[3]

[1]National Radio Astronomy Observatory. [2]University of Virginia. [3]U. Nacional Autonoma Honduras

Abstract

LIRGs (Luminous Infra-Red Galaxies) make up the brightest objects in the infrared sky and represent an important population to study galaxy evolution. Models predict episodic enhancements of the total star formation of the system as the merger progresses. We know the molecular gas is the fuel for star formation, which explains the empirical correlation seen between the star formation rate and molecular gas surface densities in galaxies, described by the Kennicutt-Schmidt relation: $\Sigma_{SFR} = \Sigma_{mol.}^{N}$, where N ~1.4 (Schmidt 1959, Kennicutt 1998). Most studies of this relation have been done using integrated measurements (Kennicutt 1998, Kennicutt & De Los Reyes 2021), however recent works at sub-kpc scales have found a wide range of values for N (e.g., Leroy et al. 2008, Pereira-Santaella et al. 2016). In this work, we study the K-S relation at 1.2 kpc scales in the nearby LIRG, NGC 5331. We use VLA radio continuum observations (3 GHz) to trace unobscured SF, as opposed to UV and/or Halpha, which suffer greatly from dust obscuration, especially in U/LIRGs, and ALMA CO (1-0) line emission observations to derive the molecular gas properties of this local LIRG. We compare this to published values of other LIRGs, ULIRGs, and local circumnuclear disks (integrated values across the whole system). Our final goal is to replicate this study in as many local U/LIRGs as possible, to study how star formation changes with merger states.

Probing the efficiency of star formation at different epochs

Dr. Jonathan Freundlich

Observatoire astronomique de Strasbourg

Abstract

Observations show a peak of star formation ten billion years ago, around redshift z=2. To understand star formation processes at different epochs and assess their efficiency, it is crucial to probe the gas reservoirs from which stars are formed. Furthermore, environment plays a crucial role in galaxy evolution and could affect both the amount of gas available and the efficiency of star formation. I will present recent molecular gas observations with the 30m telescope, NOEMA and ALMA in typical star-forming galaxies during the winding down of star formation at z=0.5-0.8, in galaxies with measured circumgalactic outflows or inflows at z=0.6-1.1, and in a galaxy group at z=0.7 where diffuse ionized gas emission may indicate gas expelled by tidal interactions, stripping, or outflows. Moving towards higher redshifts, I will also present resolved star formation efficiency measurements at z~4.5 with ALMA. Synergies between JWST and ALMA will allow to study how stellar and gas distributions are interconnected in distant galaxies, while SKA and its precursors will enable molecular gas observations at very high redshift and to probe the atomic gas up to the peak epoch of star formation, thus providing a much more complete picture of gas and star formation processes in galaxies.

Cold gas formation within an HI shell in the Magellanic Bridge from GASKAP-HI observations

Shin-Jeong Kim, Naomi McClure-Griffiths, Antoine Marchal

Australian National University

Abstract

We will present a new study that investigates the multi-phase structure of a 9 pc scale HI shell located in the Magellanic Bridge using data from the GASKAP-HI survey. Associated with the H-alpha ring DEM-171, this shell is an ideal laboratory to study the effects of dynamical events such as supernovae or stellar winds from massive stars on the HI gas properties. We decompose the HI emission spectra into multiple Gaussian components using ROHSA, which enables us to map out the cold neutral medium (CNM), lukewarm medium (UNM), and warm neutral medium (WNM) that makes up the shell. The higher CNM gas fraction (~50%) and existence of UNM gas indicate that the HI shell undergoes a phase transition in the ISM, leading to the CNM formation, likely due to the gas compression. Additionally, exisiting star clusters and young stellar objects (YSOs) catalogs support the scenario that the expansion of the HI shell can trigger subsequent star formation within the shell. This analysis illustrates the stellar feedback on the multi-phase cycle and star formation activity within the Magellanic Bridge.

Star Formation Efficiency in Nearby Galaxies Revealed with a New CO-to-H_2 Conversion Factor Prescription

Yu-Hsuan Teng[1], Karin Sandstrom[1], I-Da Chiang[2], Jiayi Sun[3], Adam Leroy[4], Alberto Bolatto[5], Antonio Usero[6], Eve Ostriker[3], Miguel Querejeta[6]

[1]University of California San Diego. [2]Academia Sinica, Institute of Astronomy and Astrophysics. [3]Princeton University. [4]Ohio State University. [5]University of Maryland. [6]Observatorio Astronómico Nacional (IGN)

Abstract

Star formation in galaxies is governed by the amount of molecular gas and the efficiency that gas is converted into stars. However, assessing the amount of molecular gas relies on the CO-to-H_2 conversion factor (α_{CO}), which is known to vary with molecular gas conditions like density, temperature, and dynamical state – the same conditions that also alter star formation efficiency (SFE). The variation of α_{CO} thus causes major uncertainties in current molecular gas and SFE measurements. Using multi-band ALMA observations of CO isotopologues at ~100 pc scales, we found that α_{CO} is primarily driven by CO opacity changes and therefore shows strong correlations with observables like velocity dispersion and $^{12}CO/^{13}CO$ line ratio. Motivated by these results, we have established a new α_{CO} prescription which accounts for CO emissivity variations and verified it across a set of nearby galaxies with independent α_{CO} measurements from dust. Applying our new prescription to 65 galaxies from the PHANGS-ALMA survey, we revealed an overall 3x higher SFE in barred than non-barred galaxy centers, which is an unprecedented trend that has been obscured by past α_{CO} prescriptions. Our results suggest that the high star formation rates observed in barred galaxy centers is mainly due to an enhanced SFE, rather than a substantially increased amount of molecular gas.

How galaxies regulate their growth

Prof Deanne Fisher

Swinburne University

Abstract

I will discuss recent observational evidence that feedback driven by star formation is impacting the surrounding ISM of galaxies. It is widely agreed that theory requires star formation driven feedback to match the fundamental properties of galaxies, such as total mass, SFR and size. I will discuss recent observational results on the role of feedback in creating turbulence in galaxies, including the nearest spirals, local Universe starbursts and high-z galaxies. I will show that in starburst galaxies and spirals correlations of velocity dispersion with star formation properties are consistent with what is expected from feedback-based simulation and feedback-regulated analytic theory. Moreover, I will show that the turbulent energy in these galaxies can be fully described by feedback energy. The implication is that feedback contributes very significantly to the velocity dispersion of galaxies across all redshifts. When feedback is stronger, the gas overpowers the local potential and breaks out from the disk. I will show recent observations of M82 & NGC253 with JWST that can give extremely high-resolution observations. These observations show a significant amount of substructure, which can be used to determine the physical processes at play in outflow.

Fast Radio Bursts: mechanisms of radiation and propagation in magnetar with finite temperature electron-positron plasma

Dr. Umer Rehman

Nanjing University, P. R China. Department of Physics, Air University Islamabad Pakistan.

Abstract

Fast radio bursts (FRBs) are extensively discussed in the magnetized pair plasma of magnetars in clod plasma approximation. However, the thermal effects or finite temperature cannot be subsided in such astrophysical objects like magnetars. In this work, we derived the classical dispersion relation for the waves in a pair electron-positron plasma environment as a function of refractive index n and the frequency of the wave normalized with the typical frequency of the FRBs. We adopted the parameters of the wave propagation in the magnetar in usual range associated with the FRBs. This work initiates a theoretical model for the wave propagation in the magnetar to obtain the dispersion relation for the fluid waves in magnetized thermal plasma. The limiting case for the cold plasma waves are reproduced. In the cold plasma case, the frequency of mode and wave number can be obtained explicitly but unable to include finite temperature effects. The explicit formula we derived in this article enables an accurate evaluation of finite temperature even near the cyclotron resonance. The analytical formula then used to describe the temperature effects on the propagation of electromagnetic waves inside and outside of the magnetosphere of the magnetar.Cyclotron absorption in a strongly magnetized cannot be completely understood without considering the thermal effects of plasma fluid in the astrophysical objects like magnetar. The absorption/emission processes require stringent physical conditions related to actual physical environment is the main objective of current investigation.

[1]Institute for Space Astrophysics and Planetology (IAPS). [2]Smithsonian Astrophysical Observatory. [3]Space Telescope Science Institute. [4]University of Massachusetts. [5]Jet Propulsion Laboratory,. [6]University of Heidelberg. [7]Laboratoire AIM, Paris-Saclay

Abstract

We present a study of the relation between neutral atomic hydrogen (HI) emission at 21 cm wavelength, carbon monoxide 12CO emission, and the three-dimensional (3D) distribution of interstellar dust derived from stellar extinction observations with roughly one kiloparsec from

the Sun. We have used the histogram of oriented gradients (HOG), a machine-vision-based tool, to match the morphology in a 3D reconstruction of the dust density (3D dust) and the gas tracers' emission distribution. A high-resolution pilot study of the Taurus molecular cloud revealed a pattern in radial velocities and distances consistent with the gas's converging motions, with the near side of the cloud moving away from us at higher velocities and the far side moving at lower velocities. This convergence of flows is likely triggered by the large-scale gas compression caused by the interaction of the Local Bubble and the Per-Tau shell, with Taurus lying at the intersection of the two bubble surfaces. A lower-resolution general study of the emission from different tracers toward the Galactic plane reveals the drift motions of some clouds with respect to Galactic rotation and the relative motion of the HI and CO that we used to estimate the potential inflow of atomic material into molecular clouds.

Understanding the physical driver of CO-to-H2 conversion factor variation within starburst galaxies

Dr. Hao He

University of Bonn

Abstract

CO-to-H2 conversion (αCO) is crucial in measuring molecular gas mass. For a long time, people adopt an empirical bimodal αCO choice for normal spiral and starburst galaxies without fully understanding the physical driver behind, which according to theory, is tightly related to molecular cloud properties at small scales. I will present the first resolved αCO spatial map down to giant molecular cloud scale (~150 pc) for one of the closest starburst galaxy mergers, the Antennae using RADEX modeling on multiple CO and ^{13}CO observations from ALMA. We find that the average value of αCO in the Antennae is ~4 times lower than the Milky Way value. We further find that the primary driver for the αCO variation within the Antennae is the GMC optical depth, which is consistent with studies of centers of normal spiral galaxies. According to theory, the two measurements that could track the optical depth variation is ^{13}CO/CO ratio and CO velocity dispersion. We find both measurements show strong correlations with αCO with power-law slopes consistent with analytical predictions, while ^{13}CO/CO ratio shows a stronger correlation and could be a better αCO tracer. We further compare our αCO maps at GMC resolution with that derived at kpc resolution and find that the kpc-scale αCO values are generally two times smaller, while the ratio between the two values shows a strong anti-correlation with dense gas fraction, which suggests that the increasing fraction of diffuse medium might be another contributor to the low αCO in starburst galaxies.

Closing the feedback-feeding loop of the radio galaxy 3C 84

Prof Tom Oosterloo[1,2], Prof Raffaella Morganti[1,2], Dr Suma Murthy[3]

[1]Netherlands Institute for Radio Astronomy. [2]Groningen University. [3]Joint Institute for VLBI ERIC

Abstract

Gas accretion by a galaxy's super massive black hole (SMBH) and the energetic feedback by the accreting active galactic nucleus (AGN) on the gas around it are two tightly intertwined processes. Observations of galaxy clusters have shown how plasma jets emitted by the AGN heat the intra-cluster medium, preventing cooling of the cluster gas and thus the infall of this gas onto the SMBH. However, observations of cool-core galaxy clusters have also shown that rising plasma bubbles, inflated by the jets, can also induce local cooling of the cluster gas, leading to filaments of cold gas. The fate of these filaments is unclear, but it has been suggested they may play a role in feeding the AGN activity. We will present results of re-processed CO(2-1), HCN and HCO+ ALMA obser vations of the molecular gas in NGC 1275, the central galaxy of the Perseus cluster hosting the radio-loud AGN 3C 84. These data show, for the first time, in great detail how kpc-sized cold gas filaments originating from jet-induced cooling of cluster gas are flowing onto the circum-nuclear accretion disc of the SMBH, showing that the cooled gas does indeed play a role in feeding the AGN activity, while in addition line ratios given useful information in the physical conditions in the circum-nuclear disc. These results complete our view of the feedback loop of how an AGN can impact on its surroundings and how the effects from this impact maintain the AGN activity.

STARFORGE-UCLCHEM: coupling star cluster formation simulations to astrochemistry

Dr. Piyush Sharda[1], Dr. Stella Offner[2], Dr. Michael Grudić[3]

[1]Leiden University. [2]University of Texas at Austin. [3]Carnegie Observatories

Abstract

The importance of astrochemistry in star formation has been long recognized, however, not much work has been done in coupling astrochemistry to hydrodynamic simulations of molecular cloud collapse and star cluster formation beyond the most common molecule - CO. Several key questions on the origin of other molecules in the interstellar medium (ISM) therefore remain unanswered, and it is not yet clear which molecules can be used to trace the ever elusive molecular hydrogen - the fuel for star formation. In this talk, I will present results from the STARFORGE-UCLCHEM collaboration where we post-process state of the art radiation-MHD simulations of star cluster formation (including all four modes of stellar feedback) with exhaustive chemical networks covering 300+ species (including a comprehensive treatment of dust and ices) and 6000+ chemical reactions. In addition to the well studied molecule CO, I will talk about our findings for other so-called dense gas tracers (e.g., HCN, HCO+, N2H+, HNC) that were out of reach of previous works using reduced chemical networks. I will end by mentioning ongoing efforts to solve exhaustive chemical networks on-the-fly with hydrodynamics to accurately capture the physics of star formation in diverse environments, and uncover the mysteries of molecule formation in clouds undergoing stellar feedback.

Star Formation and Feedback in Local Luminous and Ultra Luminous Infrared Galaxies

Dr. Loreto Barcos-Munoz

National Radio Astronomy Observatory. University of Virginia

Abstract

Luminous and Ultra Luminous Infrared Galaxies (LIRGs and ULIRGs) provide a unique laboratory to study star formation and feedback in extreme conditions. They are mainly interacting, or merging, gas-rich systems that can host massive starbursts and powerful Active Galactic Nuclei (AGN) activity. U/LIRGs show star formation rates of up to a few 100 solar masses per year concentrated into their central kpc. Due to the large amounts of gas and dust surrounding their central regions, direct observations of the nuclei are often impossible at many wavelengths. Radio, sub-mm, and infrared emission are key to study their star formation and ISM properties. I will share results from high angular resolution observations with the radio telescopes VLA and ALMA of a sample of local U/LIRGs from the Great Observatories All-sky LIRG Survey. I'll show the large detection of outflows in local U/LIRGs, and how when we combine ALMA and VLA observations we can estimate whether these systems are forming stars near their maximum capacity, as predicted by theoretical models for star-forming disks supported by radiation pressure on dust, or if an AGN is powering them. I will finalize by highlighting synergies between ALMA, VLA, and recent JWST observations of a couple of local U/LIRGs.

SYMPHANY: SYnergy of Molecular PHase And Neutral hYdrogen in galaxies in A2626

Dr. Tirna Deb

Center for Astrophysics, Harvard & Smothsonian

Abstract

The morphology-density relation in galaxies suggests that the cosmic environment significantly shapes both the morphology and star formation (SF) activity of galaxies. Dense environments like galaxy groups and clusters somehow expedite the quenching of SF and the transformation of gas-rich, late-type galaxies into gas-poor early-type systems. Various gravitational perturbations, such as tidal interactions along with hydrodynamical processes like ram pressure stripping, contribute to these transformations. It is not clear, however, which of these processes are effective or dominant in which cosmic environment, and to what extent they impact the various constituents of the interstellar medium and the SF activity. Observations of neutral Hydrogen (HI) gas in galaxies reveal that the extended HI disks are notably affected by the cluster environment, leading to deficient HI reservoirs compared to field galaxies. This deficiency is less apparent for the centrally concentrated and more tightly bound molecular gas (H2). However, studies of H2 in cluster galaxies often yield conflicting results that may vary between clusters. Given that H2 gas serves as the direct fuel for star formation, understanding its response to the cluster environment is crucial for unraveling galaxy evolution in clusters and groups. I will discuss the spatial and kinematic properties of atomic and molecular gas discs, linking them to specific local environments within the A2626 galaxy cluster, and explore their connection with the galaxy's star formation history.
