

Package ‘frab’

September 16, 2026

Type Package

Title How to Add Two R Tables

Version 0.0-7

Maintainer Robin K. S. Hankin <hankin.robin@gmail.com>

Description Methods to ``add" two R tables; also an alternative interpretation of named vectors as generalized R tables, so that `c(a=1,b=2,c=3) + c(b=3,a=-1)` will return `c(b=5,c=3)`. Uses 'disordR' discipline (Hankin, 2022, <[doi:10.48550/arXiv.2210.03856](https://doi.org/10.48550/arXiv.2210.03856)>). Extraction and replacement methods are provided. The underlying mathematical structure is the Free Abelian group, hence the name. To cite in publications please use Hankin (2023) <[doi:10.48550/arXiv.2307.13184](https://doi.org/10.48550/arXiv.2307.13184)>.

x+y
```

Arith

Arithmetic methods for class "frab"

Description

The frab class provides basic arithmetic methods for frab objects. Arithmetic operations are generally dispatched to one of self-describing functions in the following list:

- `frab_negative()`

- `frab_reciprocal()`
- `frab_plus_frab()`
- `frab_multiply_frab()`
- `frab_plus_numeric()`
- `frab_multiply_numeric()`
- `frab_power_numeric()`
- `numeric_power_frab()`

The most important one is, of course, `frab_plus_frab()` which is the *sine qua non* for the whole package. But these functions are not intended for user and are somewhat unfriendly. Use the arithmetic operators, as in “`a + 2*b`” instead.

Low-level helper functions `c_frab_add()` and `c_frab_multiply()` etc. are generated by `compileAttributes()`. They call the C routines in the `src` directory. Low-level helper function `c_frab_pmax()` is documented here for consistency; but technically `c_frab_pmax()` is an “Extremes” function. They are documented at [Compare](#) and [pmax](#) respectively.

Usage

```
frab_negative(x)
frab_reciprocal(x)
frab_plus_frab(F1,F2)
frab_multiply_numeric(e1,e2)
frab_power_numeric(e1,e2)
numeric_power_frab(e1,e2)
frab_unary(e1,e2)
frab_arith_frab(e1,e2)
frab_plus_numeric(e1,e2)
frab_arith_numeric(e1,e2)
numeric_arith_frab(e1,e2)
```

Arguments

`e1, e2, x, F1, F2` Objects of class `frab`, coerced if needed

Value

Return `frab` objects

Methods

Arith `signature(e1="frab", e2="missing")`: blah blah blah

Arith `signature(e1="frab", e2="frab")`: ...

Arith `signature(e1="frab", e2="numeric")`: ...

Arith `signature(e1="numeric", e2="frab")`: ...

Arith `signature(e1="ANY", e2="frab")`: ...

Arith `signature(e1="frab", e2="ANY")`: ...

Note

There are a few peculiarities in the methods. Function `frab_plus_numeric(e1, e2)` assumes `e1` is a frab and `e2` is numeric. But if `e2` is a named vector, it is coerced to a frab; if not, a [simulated] **disordR** violation is raised.

Examples

```
(x <- frab(c(a=1,b=2,c=3)))
(y <- frab(c(b=-2,d=8,x=1,y=7)))
(z <- frab(c(c=2,x=5,b=1,a=6)))
```

```
x+y
x+y+z
```

```
x*y
```

Compare-methods

Comparison methods

Description

Methods for comparison (greater than, etc) in the **frab** package.

Frabs and sparsetables may be compared with length-one numeric vectors. Functions `frab_gt_num()` etc follow a consistent naming convention; the mnemonic is the old Fortran `.GT.` scheme [for “greater than”]. This allows one to use idiom such as `f >= 3`. For sparsetables, comparison with scalars is possible: but the result is flattened to a `disord` object (this can be confusing for two dimensional tables when the default matrix-like print method is used, because zero entries are not “real”. For example, if `s` is a sparsetable, then `s==0` will return all `FALSE`).

Comparing a frab with another frab is generally meaningless. Idiom like “`e1 >= e2`”, for example, returns an error. The only comparison that makes any sense is whether two frabs are identical: this is detected by “`e1 == e2`” and its negation “`e1 != e2`”. Internally, equality is tested in **C** using a routine written for speed (specifically, returning `FALSE` as soon as it spots a difference between its two arguments); this is modelled on its equivalent in the **spray** package. If any value is `NA`, equality checks will return `FALSE`. Functions `frab_eq()` and `c_frab_eq()` are just **R** wrappers for the **C** routine `equal()`.

Usage

```
frab_eq(e1,e2)
frab_eq_num(e1,e2)
frab_ne_num(e1,e2)
frab_gt_num(e1,e2)
frab_ge_num(e1,e2)
frab_lt_num(e1,e2)
frab_le_num(e1,e2)
num_eq_frab(e1,e2)
num_ne_frab(e1,e2)
num_gt_frab(e1,e2)
num_ge_frab(e1,e2)
num_lt_frab(e1,e2)
num_le_frab(e1,e2)
numeric_compare_frab(e1,e2)
frab_compare_frab(e1,e2)
frab_compare_numeric(e1,e2)
```

Arguments

e1, e2 Objects of class frab

Value

Generally, return a frab or a logical

Author(s)

Robin K. S. Hankin

See Also

[Arith](#)

Examples

```
rfrab()
a <- rfrab(26,sym=letters)
a[a<4] <- 100
```

Concatenate

Concatenation methods for class "frab"

Description

Concatenation does not make sense for frab objects and will return an error. For combining objects, use a+b.

Usage

```
## S4 method for signature 'frab'
c(x, ...)
```

Arguments

`x, ...` Objects to be concatenated

Value

No return value, throws an error.

Methods

`signature(x = "frab")` Method for `c()` to prevent concatenation.

dataframe	<i>Coerce a data frame to a frab</i>
-----------	--------------------------------------

Description

Coerce a data frame to a frab

Usage

```
df_to_frab(from)
## S4 method for signature 'data.frame'
as.frab(x)
```

Arguments

`x, from` Frab objects

Details

Coerces a data frame, with columns key and value, to the appropriate frab object. Repeated keys are summed.

Value

Returns a frab object or a dataframe.

Author(s)

Robin K. S. Hankin

Examples

```
as.frab(data.frame(key=letters[1:5],value=1:5))
```

Extract

*Extraction and replacement methods for class "frab"***Description**

The frab class provides basic arithmetic and extract/replace methods for frab objects.

Class *index* is taken from the excellent **Matrix** package and is a `setClassUnion()` of classes `numeric`, `logical`, and `character`.

Value

Generally, return a frab object.

Methods

```
[ signature(x = "frab", i = "character", j = "missing"): x["a"] <- 33
[ signature(x = "frab", i = "disord", j = "missing"): x[x>3]
[ signature(x = "frab", i = "missing", j = "missing"): x[]
[<- signature(x = "frab", i = "character", j = "missing", value = "ANY"): x["a"] <- 3
[<- signature(x = "frab", i = "disord", j = "missing", value = "frab"): x[x<0] <- -x[x<0];
    not implemented
[<- signature(x = "frab", i = "disord", j = "missing", value = "logical"): x[x<0] <- NA
[<- signature(x = "frab", i = "ANY", j = "ANY", value = "ANY"): not implemented
[<- signature(x = "frab", i = "disindex", j = "missing", value = "numeric"): x[x>0] <- 3
[<- signature(x = "frab", i = "character", j = "missing", value = "logical"): x["c"] <-
    NA
```

Double square extraction, as in `x[[i]]` and `x[[i]] <- value`, is not currently defined. In replacement methods, if value is logical it is coerced to numeric (this includes NA).

Special dispensation is given for extraction of a frab with a length zero index, as in `x[NULL]`, which returns the empty frab object.

Author(s)

Robin K. S. Hankin

Examples

```
frab(setNames(seq_len(0), letters[seq_len(0)]))
```

```
a <- rfrab(26, sym=letters)
a<4
a[a<4]
a[a<4] <- 100
a
```

```

x <- rfrab()
values(x) <- values(x) + 66

x <- rfrabb()
v <- values(x)
v[v<0] <- abs(v[v<0]) + 50
values(x) <- v

names(x) <- toupper(names(x))
x

```

frab

Creating frab objects

Description

Package idiom for creating frab objects

Usage

```

frab(x)
as.frab(x)
is.frab(x)
list_to_frab(L)

```

Arguments

x	object coerced to, or tested for, frab
L	List of two elements, a numeric vector named values and a character vector named names

Details

Function `frab()` is the creation method, taking a named numeric vector as its argument; it is the only function in the package that actually calls `new("frab", ...)`.

Function `as.frab()` tries a bit harder to be useful and can coerce different types of object to a frab. If given a list it dispatches to `list_to_frab()`. If given a table it dispatches to `table_to_frab()`, documented at `table.Rd`; and if given a data frame it dispatches to `df_to_frab()`, documented at `dataframe.Rd`.

Value

Returns a frab, or a boolean

Author(s)

Robin K. S. Hankin

See Also[frab-class](#)**Examples**

```

frab(c(x=6, y=6, z=-4, u=0, x=3))

as.frab(c(a=2, b=1, c=77))

as.frab(list(names=letters[5:2], values=1:4))

x <- rfrab()
y <- rfrab()
x + y

```

frab-class

*Class “frab”***Description**

The formal S4 class for frab objects

Usage

```

## S4 method for signature 'frab'
namedvector(x)

```

Arguments

x Object of class frab

Objects from the Class

Formal class *frab* has a single slot x which is a named numeric vector.

The class has three accessor methods: `names()`, `values()`, and `namedvector()`.

Author(s)

Robin K. S. Hankin

Examples

```
new("frab",x=c(a=6,b=4,c=1))  # formal creation method (discouraged)

frab(c(a=4,b=1,c=5))  # use frab() in day-to-day work

frab(c(a=4,b=0,c=5))  # zero entries are discarded

frab(c(a=4,b=3,b=5))  # repeted entries are summed

frab(c(apple=4,orange=3,cherry=5))  # any names are OK

x <- frab(c(d=1,y=3,a=2,b=5,rug=7,c=2))
(y <- rfrab())

x+y          # addition works as expected
x + 2*y      # arithmetic
x>2          # extraction
x[x>3] <- 99 # replacement

# sum(x)      # some summary methods implemented
# max(x)
```

misc

Miscellaneous functions

Description

This page documents various functions that work for frabs, and I will add to these from time to time as I add new functions that make sense for frab objects. To use functions like `sin()` and `abs()` on frab object `x`, work with `values(x)` (which is a `disord` object). However, there are a few functions that are a little more involved:

- `length()` returns the length of the data component of the object.
- `which()` returns an error when called with a frab object, but is useful here because it returns a `disind` when given a Boolean `disord` object. This is useful for idiom such as `x[x>0]`
- Functions `is.na()` and `is.notna()` return a `disind` object
- Function `abs()` returns a frab with entries being the absolute value of those of its argument
- `sort()` does not make sense for frab objects.

Usage

```
## S4 method for signature 'frab'
length(x)
```

Arguments

x Object of class frab

Value

Generally return frabs

Note

Constructions such as `!is.na(x)` do not work if `x` is a frab object: this is because `is.na()` returns a `disind` object, not a logical. Use `is.notna()` to identify elements that are not NA.

Author(s)

Robin K. S. Hankin

See Also

[extract](#)

Examples

```
(a <- frab(c(a=1,b=NA,c=44,x=NA,h=4)))
is.na(a)

(x <- frab(c(x=5,y=2,z=3,a=7,b=6)))
which(x>3)
x[which(x>3)]
x[which(x>3)] <- 4
x

is.na(x) <- x<3
x
x[is.na(x)] <- 100
x

y <- frab(c(a=5,b=NA,c=3,d=NA))
y[is.notna(y)] <- 199
y
```

namedvector

Named vectors and the frab package

Description

Named vectors are closely related to frab objects, but are not the same. However, there is a natural coercion from one to the other.

Usage

```
as.namedvector(v)
is.namedvector(v)
is.namedlogical(v)
is.unnamedlogical(v)
is.unnamedvector(v)
```

Arguments

<code>v</code>	Argument to be tested or coerced
----------------	----------------------------------

Details

Coercion and testing for named vectors. Function `nv_to_frab()`, documented at `frab.Rd`, coerces a named vector to a `frab`.

Value

Function `is.namedvector()` returns a boolean, function `as.namedvector()` returns a named vector.

Note

The issue of named logical vectors in the ‘frab’ package is discussed briefly at ‘`inst/wittgenstein.Rmd`’.

Author(s)

Robin K. S. Hankin

Examples

```
x <- c(a=5, b=3, c=-2, b=-3, x=33)
is.namedvector(x)
as.namedvector(frab(x))

x <- c(a=5, b=3, c=-2)
y <- c(p=1, c=2, d= 6)

x
y
x+y

frab(x) + frab(y)
```

pmax

Parallel maxima and minima for frabs

Description

Parallel (pairwise) maxima and minima for frabs.

Usage

```
pmax_pair(F1,F2)
pmin_pair(F1,F2)
pmax_dots(x, ...)
pmin_dots(x, ...)
## S4 method for signature 'frab'
pmax(...)
## S4 method for signature 'frab'
pmin(...)
```

Arguments

F1, F2, x, ... Frab objects

Details

Pairwise minima and maxima for frabs, using names as the primary key.

Functions `pmax_pair()` calls `c_frab_pmax()` and `pmin_pair()` use

Functions `pmax()` and `pmin()` use the same mechanism as `cbrob()` of the **Brobdignag** package, originally due to John Chambers (pers. comm.)

Value

Returns a frab object

Author(s)

Robin K. S. Hankin

Examples

```
x <- rfrab()
y <- rfrab()
```

print

Methods for printing frabs

Description

Methods for printing frabs nicely

Usage

```
## S4 method for signature 'frab'
show(object)
frab_print(object)
```

Arguments

object An object of class frab

Details

The method is sensitive to option `frab_print_hash`. If `TRUE`, the hash code is printed; otherwise it is not.

Function `frab_print()` returns its argument, invisibly.

There is special dispensation for the empty frab object.

Value

Returns its argument, invisibly

Author(s)

Robin K. S. Hankin

Examples

```
print(rfrab()) # default

options(frab_print_hash = TRUE)
print(rfrab()) # prints hash code

options(frab_print_hash = NULL) # restore default
```

`rfrab`*Random frabs*

Description

Random frab objects, intended as quick “get you going” examples

Usage

```
rfrab(n = 9, v = seq_len(5), symb = letters[seq_len(9)])  
rfrabb(n = 100, v = -5:5, symb = letters)  
rfrabbb(n = 5000, v = -10:10, symb = letters, i=3)
```

Arguments

<code>n</code>	Length of object to return
<code>v</code>	Values to assign to symbols (see details)
<code>symb</code>	Symbols to use
<code>i</code>	Exponentiating index for <code>rfrabbb()</code> . Symbols in returned value will be <code>i</code> concatenated elements of <code>symb</code>

Details

What you see is what you get, basically. If a symbol is chosen more than once, as in, `c(a=1,b=2,a=3)`, then the value for `a` will be summed.

Use function `rfrab()` for a small, easily-managed object; `rfrabb()` and `rfrabbb()` give successively larger objects.

Value

Returns a frab object

Author(s)

Robin K. S. Hankin

Examples

```
rfrab()
```

Description

Package idiom for creating and manipulating sparsetable objects

Usage

```
sparsetable(i,v=1)
rspar(n=15,l=3,d=3)
rspar2(n=15,l=6)
rsparr(n=20,d=6,l=5,s=4)
sparsetable_to_array(x)
array_to_sparsetable(x)
sparsetable_to_frab(x)
## S4 method for signature 'sparsetable'
index(x)
## S4 method for signature 'sparsetable'
values(x)
## S4 method for signature 'sparsetable'
dimnames(x)
## S4 method for signature 'sparsetable'
dim(x)
```

Arguments

<code>x</code>	In functions like <code>index()</code> , an object of class <code>sparsetable</code>
<code>i, v</code>	In standard constructor function <code>sparsetable()</code> , argument <code>i</code> is the index matrix of strings, and <code>v</code> a numeric vector of values
<code>n, l, d, s</code>	In functions <code>rspar()</code> , <code>rspar2()</code> , and <code>rsparr()</code> , <code>n</code> is the number of terms, <code>l</code> the number of letters, <code>d</code> the dimensionality and <code>s</code> the number of distinct marginal values to return

Details

Most functions here mirror their equivalent in the **spray** package [which the C code is largely copied from] or the `frab` functionality. So, for example, `num_eq_sparsetable()` is the equivalent of `num_eq_spray()`.

The print method treats arity-2 sparsetable objects differently from other arities. By default, arity-2 sparsetable objects are displayed as two-dimensional tables. Control this behaviour with option `print_2dsparsetables_as_matrices`:

```
options("print_2dsparsetables_as_matrices" = FALSE)
```

The default value for this option, non-`FALSE` (including its out-of-the-box status of “unset”), directs the print method to coerce arity-2 sparsetable objects to two-dimensional tables before printing. If this option is `FALSE`, arity-2 sparsatables are printed using matrix index form, just the same as any other arity.

Functions `rspar()`, `rspar2()`, and `rsparr()` create random sparsetable objects of increasing complexity. The defaults are chosen so that the returned frabs are of sensible sizes.

Function `drop()` takes a sparsetable object of arity one and coerces to a frab object.

Function `dim()` returns a named vector, with names being the `dimnames` of its argument.

Extraction and replacement methods are a subset of **spray** methods, but most should work. There is special dispensation so that standard idiom for arrays [e.g. `x['a', 'b', 'a']` and `x['a', 'b', 'a'] <- 55`] should work as expected, although the general expectation is that access and replacement use (character) matrices and an index object. However, indexing by `disord` and `disindex` objects should also work [e.g. `x[x>7]`].

The **spray** source code and the sparsetable functionality have about 90% overlap; there were enough small differences between the codes to make it worth maintaining two sets of source code, IMO.

There is a discussion of package idiom in the vignette, `vignette("frab")`.

Note

The pronunciation of “sparsetable” has the emphasis on the first syllable, so it rhymes with [British river-port town] “Barnstaple”.

sparsetable(matrix(sample(letters[1:4], 39, replace=TRUE), ncol=3), 1:13)

(x <- rspar2(9))
(y <- rspar2(9))
x + y

x["KT", "FF"] <- 100
x

rsparr()

a <- rspar(d=4)
asum(a, "Feb")
```

Summary-methods	<i>Methods for Function Summary</i>
-----------------	-------------------------------------

Description

Methods for **S4** function Summary in the **frab** package. Currently, only `max()`, `min()`, `range()` and `sum()` are defined, and these operate in the natural way on the elements of a `frab`. Note that these functions are not susceptible to **disordR** violations.

Methods

`signature(x = "frab")` Dispatches to `max(values(x))` etc.

Examples

```
a <- rfrab()
a
max(a)
min(a)
range(a)
```

table	<i>Tables and frab objects</i>
-------	--------------------------------

Description

Various methods and functions to deal with tables in the **frab** package.

Usage

```
## S4 method for signature 'frab'
as.table(x,...)
table_to_frab(x)
```

Arguments

- `x` Object of class `frab` or `table`
- `...` Further arguments, currently ignored

Details

If a `frab` object has non-negative entries it may be interpreted as a table. However, in base **R**, table objects do not have sensible addition methods which is why the **frab** package is needed.

Function `is.1dtable()` checks for its argument being a one-dimensional table. The idea is that a table like `table(sample(letters,30,TRUE))`, being a table of a single observation, is accepted but a table like `table(data.frame(rnorm(20)>0,rnorm(20)>0))` is not acceptable because it is a *two*-dimensional contingency table.

Value

Generally return a table or frab.

Note

The order of the entries may be changed during the coercion, as per **disordR** discipline. Function `as.frab()` takes a table, dispatching to `table_to_frab()`.

Author(s)

Robin K. S. Hankin

Examples

```
X <- table(letters[c(1,1,1,1,2,3,3)])
Y <- table(letters[c(1,1,1,1,3,4,4)])
Z <- table(letters[c(1,1,2,3,4,5,5)])

X+Y # defined but nonsense

# X+Z # returns an error

as.frab(X) + as.frab(Y) # correct answer

plot(as.table(rfrab()))
```

zero

The zero frab object

Description

Test for a frab object's being zero (empty).

Usage

```
zero(...)
is.zero(x)
is.empty(x)
```

Arguments

<code>x</code>	Object of class frab
<code>...</code>	Further arguments (currently ignored)

Details

Function `zero()` returns the empty frab object; this is the additive identity 0 with property $x + 0 = 0 + x = x$.

Function `is.zero()` returns TRUE if its argument is indeed the zero object.

Function `is.empty()` is a synonym for `is.zero()`. Sometimes one is thinking about the free Abelian group, in which case `is.zero()` makes more sense, and sometimes one is thinking about maps and tables, in which case `is.empty()` is more appropriate.

Value

Function `zero()` returns the zero frab object, function `is.zero()` a Boolean

Author(s)

Robin K. S. Hankin

Examples

```
zero()
zero() + zero()

x <- rfrab()

x + zero() == x

is.zero(zero())
```
